Detoxification is most commonly thought of as a biotransformation process for organic or immune complex clearance, but specific pathways exist for the detoxification of toxic metals. They appear to have the same polymorphic enzymatic functionality as other enzyme systems and the consequent SNP (single nucleotide polymorphism) variability. Unfavorable SNPs will commonly lead to an elevated burden of toxic metals without excessive exposure. For example, some autistic patients have elevated provoked urine toxic metals, while the rest of the family tests in the normal range.⁷² These same children will often have dysbiosis that is very difficult to eradicate. Upon the discovery of the toxic load and treatment thereof, the dysbiosis can generally be treated more successfully.

Optimization of Absorption

Absorption is accomplished by several means. Most are under regulatory control. This would suggest that mass action and Le Chatelier's principle would dictate mitigation of absorption difficulties with presentation of adequate substrate for the receptor/transporter molecule and/or its cofactors. Also, some forms of absorption are energy dependent. There may be direct or indirect energy utilization. In any case, a metabolic disturbance that adversely affects energy balance will negatively affect absorption.

An important engine for absorption is the Na/K-ATPase pump. This pump powers many of the energy-dependent absorption pathways. Unfortunately, most of the work on Na/K-ATPase has been done on skeletal muscle and not on enterocytes. Nonetheless, regulation of Na/K-ATPase has been shown to be similar across tissue types. Magnesium, a commonly deficient mineral,⁷³

is required for active transport into the cell by Na/K-ATPase. Magnesium-deficient animals and humans have been found to have reduction in Na/K-ATPase activity.⁷⁴ Potassium, a key ion in the Na/K-ATPase pump, is frequently deficient, especially in the presence of certain diuretics. Deficiency of potassium has been associated with poor Na/K-ATPase activity.⁷⁵ Thyroid hormone is involved in the expression of genes that encode for Na/K-ATPase. Problems with thyroid function, whether low thyroid hormone or poor peripheral conversion of T_4 to T_3 , may adversely affect activity of this critical absorption pathway. Insulin is a potent stimulator of Na/K-ATPase activity. The prevalence of insulin resistance in our culture may play an untoward role in nutrient absorption because of its regulation of the ATPase enzyme. Additionally, catecholamines play a significant role in the regulation of ATPase activity.⁷⁶ It may be that, in the chronically unwell, adrenal insufficiency could lead to underactivity of Na/K-ATPase activity, leading to poor absorption. Adrenal insufficiency may play another role in absorption abnormality by altering glucocorticoid metabolism. Glucocorticoid steroids (GCS) are potent stimulators of Na/K-ATPase. In adrenal exhaustion, the low concentration of GCS may inhibit this enzyme.⁷⁷

Even this very brief review of energy-dependent nutrient absorption makes it clear that optimization of all elements of the functional medicine web is critical to improving the performance of the digestion and absorption system.

Modulation of Immune Interactions

As we know, a majority of the lymphatic tissue in the body is closely associated with the gut. The gut associated lymphoid tissue or GALT (discussed further on in this chapter) is estimated to represent as much as 70% of the total body reserves of lymphoid tissue. Gut pathology has also been associated with dysregulation of the GALT.⁷⁸ Additionally, systemic symptoms and disease states have been associated with this same dysregulation.⁷⁹ Oral tolerance is an important mechanism of immune regulation and appears to be regulated by the development of a healthy GI microflora and proper timing of antigen presentation. (See Figure 28.1.) Breast feeding appears to optimize both of these variables. In the perinatal period, this appears to be an important mechanism for immune regulation.⁸⁰

Figure 28.1 Developing oral tolerance

The events that lead to cell priming and Th1/Th2 development are complex. (A thorough discussion of issues surrounding immune and inflammatory balance can be found in Chapter 23.) It had been thought that the cytokine environment was the primary skewing agent. It is now recognized that the cytokine environment probably amplifies the skewing, but the antigen itself (and the way it is presented) is the primary skewing agent.⁸¹ This suggests that an intact gut mucosa will have a role to play in Th skewing. If antigen concentration at the presentation site is controlling this balance, and if improving the barrier function of the gut will limit the type and quantity of antigen presentations, then Th development will be affected.

In fact, the part played by HLA antigens and their interaction with GI microflora has been explored.⁸² *Klebsiella* has been implicated in the pathogenesis of ankylosing spondylitis (AS), but not all persons with *Klebsiella* have AS. HLA B-27 has also been implicated in the pathogenesis of AS, yet not all persons with HLA B-27 have AS. From a functional medicine perspective, it seems likely that—in those persons with HLA B-27 and GI colonization with *Klebsiella* and leaky gut—the environment for the development of AS is ripe. The increased interaction of *Klebsiella* and the GALT will intensify the likelihood of cross-reactive immune responses between *Klebsiella* and human determinate sites in the spine, thus resulting in the clinical features of AS.

Laboratory Testing in Gastrointestinal Functional Medicine

Gastric Analysis

Gastric analysis is basically an assessment of gastric pH. The normal pH of the stool is between 1 and 2.3. Acid secretion is stimulated by the vagus nerve, the mechanical distention of the stomach, and partially digested proteins.

Normally functioning stomach: Once the pH reaches approximately 2, feedback mechanisms turn off the parietal cell acid secretion mechanism. pH control of the stomach is essential to optimal digestion, as described in other sections of this text. Additionally, pepsin 1 and 2 function optimally at a pH between 2 and 3. Above 5, pepsin is essentially inactive.

Gastric analysis can be accomplished in several ways. The Heidelberg analysis is performed when the patient swallows a small capsule and the gastric acidity is tracked by radio telemetry.⁸³ Various protocols exist to challenge the acid-secreting capacity of the gastric mucosa during the test.

Another option for gastric analysis:

1. The patient is put on a food and liquid fast for approximately eight hours.
2. A small caliber nasogastric (NG) tube is placed via the nostril into the stomach.
3. In the case of an NG tube, an aspirate is collected and the pH is checked. Normal fasting pH should be between 1 and 2.3.
4. The patient is challenged with bicarbonate solution (various protocols exist). The pH should reach 7 within five minutes after ingestion.
5. Patient should be lying on the left side (in an effort to keep the bicarb solution in the stomach as long as possible).
6. The pH should be measured by aspiration every five minutes.
7. The pH should reach less than 2 within 20 minutes.
8. Repeat up to four times to measure reserve of parietal cell activity.

Fat Absorption Test

If secretions from the pancreas and liver are adequate, absorption of dietary fat is almost complete. To assess for adequacy of digestion and absorption of fats, a fecal fat analysis can be done. Excessive fecal fat is

called steatorrhea. This condition should be suspected when the patient has large, “greasy,” and foul smelling stool. Steatorrhea can be caused by digestive disorders, such as failure of the pancreas or biliary secretion system,⁸⁴ by absorption problems, or by transport of fat across the intestinal mucosal membrane. While this test will help with the diagnosis of gross or profound fat malabsorption, it is not sensitive to subtle problems of fat absorption.

Procedure.^{85,86}

1. A diet consisting of approximately 100 g of fat per day should be started three days prior to collection of stool and should end on the last day of stool collection.
2. No ethanol should be consumed during this time.
3. Collect stool for 72 hours commencing on the third day of the high-fat diet.
4. Send stool for fat analysis.
5. Normal range is 5–7 g of fat per 24 hours.

Enzyme Function

Various schemes have been proposed for pancreatic enzyme testing. Recently, an enzyme known as pancreatic elastase 1 (PE1) has been shown to have a very high correlation with more invasive tests to determine pancreatic function. PE1 is unique to the human pancreatic secretion and is not affected by pancreatic enzyme supplements. For these reasons, PE1 is a good test of baseline pancreatic function.^{87,88} Most healthy patients will have a PE1 greater than 500 mcg/g. A PE1 greater than 200 mcg/g is considered normal. A PE1 of 100–200 mcg/g shows mild to moderate dysfunction. A PE1 of less than 100 mcg/g reflects moderate to severe pancreatic hypofunction. Chymotrypsin is another marker for testing pancreatic function. While it is affected by enzyme supplementation, it may be a good guide to follow the adequacy of enzyme supplementation.⁸⁹ Both chymotrypsin and fecal elastase-1 can be determined by a single random stool collection.⁹⁰

Microbiology Testing

The merits of optimal GI microflora are discussed in the next part of this chapter. Of the nearly 400 species of bacteria that inhabit the gastrointestinal system, most of them are anaerobic. Bifidobacteria account for approximately ¼ of the total flora. Other

species found in large amounts include acidophilus and *E. coli*. Although it is well known that overgrowth of a pathogen can cause problems, it is less well understood that the presence of *beneficial* bacteria, or the substances that favor the growth of beneficial bacteria, can reduce the risk of conditions associated with inflammation.^{91,92,93,94}

Stool culture has been used for years to assess the relative balance of beneficial vs. harmful microbes. Aerobic culture is common and readily available. It may be used to assess for beneficial and pathogenic bacteria, as well as for imbalance.^{95,96,97}

Measurements of Inflammation in the Gut

Eosinophil protein X (EPX): EPX is a measure of eosinophil activity within the intestinal mucosa that can be evaluated by a non-invasive test on a stool sample. EPX is elevated in inflammatory bowel disease and can be useful for evaluating disease activity and predicting relapse.^{98,99,100} Levels can also be elevated in a number of other common conditions (e.g., intestinal parasitic disease,¹⁰¹ atopic dermatitis,¹⁰² and eosinophilic gastroenteritis¹⁰³), however, so its specificity is not very high.

Calprotectin: Calprotectin is a marker of leukocyte activity. It is well correlated with indium-111 (¹¹¹In) labeled lymphocyte excretion testing and endoscopic biopsy assessment of leukocyte activity that is evaluated via a simple stool sample. Elevated calprotectin can help distinguish irritable bowel syndrome from inflammatory bowel disease^{104,105} and is also seen in bowel cancer and polyp disease. Elevated calprotectin levels can also predict relapses of inflammatory bowel disease.¹⁰⁶

Intestinal Permeability Testing

Mannitol-lactulose test: Mannitol is a small, non-metabolized sugar that is readily absorbed and excreted in urine unchanged. Lactulose is a large, non-metabolized sugar that is generally not absorbed and is excreted in stool. Lactulose can be absorbed paracellularly if the tight junctions between cells are “leaky.” This test uses a known mixed dose of mannitol and lactulose. The recovery of each in urine is related to cellular absorption (mannitol) and paracellular leakiness (lactulose). The degree to which each is recovered is related to the degree of impaired barrier function of the GI mucosa;

this relationship has been demonstrated in a variety of conditions.^{107,108,109,110,111}

Food Allergy Testing

Another way of assessing leaky gut is via food allergy testing. If a patient is allergic to a large number of foods tested, leaky gut may be implicated. When intestinal permeability is increased, abnormal interactions between the gut luminal content and the immune system are more common.¹¹² If these interactions involve partially-digested food constituents, food allergy may develop. In cases of multiple food allergies, one should have a high degree of suspicion about leaky gut. Likewise, if a patient is placed on an elimination diet and initially improves, only to regress in one to six months, leaky gut should be suspected. The patient may have improved due to a lower overall immune load and then relapsed when the unresolved leaky gut resulted in more interactions with the new or resumed foods, resulting in allergy/intolerance of these new substances. A fully referenced discussion of leaky gut is presented in Chapter 31.

Visualization

Esophagogastroduodenoscopy (EGD).¹¹³ This is a fiber optic test that allows visualization of the mucosa of the esophagus, stomach, and duodenum, and also biopsy evaluation. Biopsies may help with finding abnormalities that are not readily apparent to the naked eye. At times, the mucosa will appear normal, but a biopsy will show microscopic inflammatory changes or infiltrates with lymphocytes, eosinophils, or other leukocytes. In the case of eosinophils, it is suggestive of allergic or parasitic phenomenon. A number of chemical tests may also be performed on the biopsy, the most common of which is the urease test for detecting *H. pylori*. The gold standard for diagnosing celiac disease is a biopsy of the duodenum.

Colonoscopy.¹¹⁴ This test allows fiber optic visualization of the colon. The same observations made about EGD apply. Biopsies can show inflammation and can differentiate inflammatory from non-inflammatory changes. The character of the infiltrate can also be helpful. As an example, an infiltrate of predominantly eosinophils may suggest an allergic or parasitic process, and cryptitis is typically seen in inflammatory bowel disease.

Summary

Based on the above discussion, we can identify some general guidelines for optimizing digestion and absorption, although it's important to remember that treatment in the functional medicine paradigm must be adapted to each patient's antecedents, triggers, mediators, and genetic predispositions.

1. An oligoantigenic elimination diet is an important first step, and can have significant clinical impact. Patients should follow the protocol shown in the Appendix for at least four weeks to clear the GI environment of antigens and toxic materials. Then, a careful and paced reintroduction of foods should be undertaken. This reintroduction is a vital part of the treatment intervention. The more careful the reintroduction of food types, the more specific the information gained from the challenge process.
2. The reduction of inflammation is extremely important. Use balanced anti-inflammatory strategies that do not increase leakiness of the gut. Many anti-inflammatory herbs and food have been identified. A complex and multi-targeted approach seems most likely to be successful.
3. The reduction of gut permeability should help to reduce dysfunctional immune/gut lumen interactions. This may reduce autoimmune activity by reducing molecular mimicry, and may balance Th1 vs. Th2 skewing. It will also reduce inflammatory immune complex formation. Several herbs and nutrients are known to reduce gut permeability, and the use of the elimination diet alone has been shown to reduce gut permeability.
4. Optimization of digestive constituents helps to break down food components, reduce the antigenicity of food constituents, and optimize the chyme for absorption. Enzymes typically have a fairly narrow pH range in which they operate efficiently. It is important to keep this in mind as you attempt to replete a patient with enzyme deficiency. Repletion will improve sterilization of the food bolus and help with unfolding of proteins for further enzymatic digestion. Bile is important for the saponification of fats. With the prevalence of gall bladder disease, relative bile salt deficiency is common. While the liver may be making bile salts normally, they are trickled into the duodenum rather than pumped in as a bolus at the appropriate time during fat ingestion.
5. Optimization of absorption by insuring adequate enzymatic and energy cofactors will improve repair and regeneration at all levels. The primary motive force for energy-dependent absorption is via the Na/K-ATPase pump. Steps should be taken to optimize the efficiency of this system.
6. Balancing immune interactions will have local and systemic effects on health. Leaky gut and abnormal immune interaction with the gut lumen contents are sources of autoimmunity that can be influenced through the use of herbal and food-based strategies designed to stabilize immune components. In addition, enzymes may be capable of cleaving immune complexes and reducing their inflammatory activity.
7. Stress management. While many of the so called "functional GI disorders" have now been found to have organic causes, the mind is still an active participant in the process. "Stress and emotions may trigger neuroimmune and neuroendocrine reactions via the brain-gut axis."¹¹⁵ Helping patients achieve a sense of control over their illness can be powerful. Hypnosis, meditation, and other stress-management techniques may have a positive impact on GI health.

Balance of Flora, GALT, and Mucosal Integrity

Patrick Hanaway, MD

Introduction

The gastrointestinal tract, the tube within a tube, connects us to our environment through a dynamic interface that is larger than a doubles tennis court. Over the course of our lifetimes, we will ingest many tons of macronutrients, micronutrients, chemicals, and toxins. (Experts vary on the tonnage, but figures range from 30 to 60 tons of food consumed in the lifetime of the average well-nourished adult.¹¹⁶) These materials provide the building blocks for everything human. Imbalances in our functional ability to make the most of these nutrients have ramifications for every aspect of our being. Imbalance in the gastrointestinal system has implica-

tions that extend far beyond gastrointestinal symptoms; thus, the clinician must be vigilant to gastrointestinal dysfunction in nearly every clinical interaction.

Classically, the functions of digestion and absorption are considered the principal roles of the gastrointestinal epithelium. The quality of discernment that Traditional Chinese Medicine (TCM) attributes to the “Small Intestine Official” is manifested through its ability to separate the wheat from the chaff,¹¹⁷ but also in the embedded relationship of the innate and adaptive immune system within the gastrointestinal system. The impact of diet and nutrients on the balance of commensal flora is considerable. Digestion and absorption provide proper macronutrients and micronutrients, while responses such as appropriate physiologic inflammation, the development of oral tolerance, the production of neurochemicals by the “second brain” (Michael Gershon’s term for the enteric nervous system¹¹⁸), and the appropriate excretion of waste must all function effectively and in balance with each other in order to foster health and well-being.

Dysfunction within the gastrointestinal system manifests in typical digestive diseases such as gastroesophageal reflux disease (GERD), irritable bowel syndrome (IBS), inflammatory bowel disease (IBD),¹¹⁹ non-alcoholic steatohepatitis (NASH),¹²⁰ and even colorectal cancer (CRC).¹²¹ Gastrointestinal dysfunction can also manifest as imbalanced immunologic function, thus creating and/or contributing to both atopic illness¹²² (including allergy and asthma) and autoimmune dysfunction¹²³ (including rheumatoid arthritis, type 1 diabetes, and Hashimoto’s thyroiditis). Other diseases of immune dysregulation and gastrointestinal dysfunction now include the autism spectrum disorders.¹²⁴ The evolution of these diseases begins long before the presentation of symptoms and thus the opportunity for prevention and early intervention can have tremendous impact on the burden of suffering and disease.

Dietary approaches provide the most effective means of restoring balance within the gastrointestinal system and there are many opportunities to bring these tools to patients. However, the profound dietary changes experienced by humans over the past 10,000 years—and greatly accelerated over the past 100 years—conflict with the nutritional input that our genetic structure evolved to maximize.¹²⁵ This discor-

dance creates a much more complex array of clinical needs that require support for the whole being to regain balance and optimal function.

Functional medicine allows us to intervene along a continuum from illness to wellness, where the approach is of value at each level—addressing treatment of disease, relief of symptomatic imbalance even before pathologic disease has manifested, prevention, and optimal wellness. The determination of appropriate therapeutic approaches is contingent upon the degree of imbalance that is present. Observation of history, signs, and symptoms (including noting the patient’s own antecedents, triggers, and mediators) helps with initial understanding. Diagnostic testing helps to further illuminate and clarify the degree of dysfunction.

Diagnostic considerations include, first and foremost, an extensive health history to gain an understanding of dietary inputs, utilization of antibiotics, laxatives, fiber, herbs, etc. In addition, one must elicit the current pattern of bowel movements, including frequency, history, abdominal pain, gas, bloating, relationship to meals, and duration. It is amazing how many patients consider their altered bowel movements to be normal. Western medicine does not have a defined norm of bowel movement frequency, while other forms of healing such as Ayurveda and Traditional Chinese Medicine view the regular functioning of the gastrointestinal tract to be a critical barometer of health and well-being, with one well-formed bowel movement per day as the norm.¹²⁶ Other diagnostic considerations include the evaluation of stool to gather information on parameters of digestion, absorption, inflammation, infection, and altered gut flora (known as dysbiosis).

Let us look more closely at the specific imbalances faced by clinicians as we examine how they manifest in pathophysiology and how they can be balanced to optimize health.

Gut Flora

Cordain¹²⁷ describes the dietary patterns most common today, and compares them with the characteristics of ancestral diets. He notes alterations in glycemic load, fiber content, essential fatty acid composition, pH balance, and macronutrient/micronutrient composition, all of which have tremendous effects on the balance of the commensal flora within the gastrointestinal tract.

The critical functions of the commensal flora are:

- Metabolic processes:
 - fermentation,
 - vitamin synthesis,
 - energy production;
- Trophic stimulation:
 - epithelial cell differentiation,
 - immunomodulation;
- Pathogen protection:
 - competing for nutrients, space, adherence,
 - producing bacteriocidins.

New evidence is evolving that the persistent interactions between host and bacteria that take place in the gut may constantly reshape the immune system.¹²⁸ Clinicians see the profound effects of altered commensal flora in the nearly 15% of the population who are affected by IBS, a functional GI disorder.¹²⁹ It is also becoming clear that the immune dysregulation of IBD is profoundly influenced by the role of gut flora.¹³⁰ Symptomatic evaluation of patients who have alterations in bowel patterns defined by the Rome II Criteria (see Table 28.1) meet the definition of IBS.¹³¹

Table 28.1 IBS—Rome II Criteria

12 or more weeks of continuous or recurrent abdominal pain or discomfort,

plus at least two of the following:

1. Relieved by defecation

and/or

2. Associated with change in frequency of stool

and/or

3. Associated with a change in form (appearance) of stool

and an absence of alarm symptoms:

- Anemia
- Fever
- Heme-positive stools
- New or recent onset if > 50 years old
- Nocturnal symptoms
- Palpable abdominal or rectal mass
- Persistent diarrhea or severe constipation
- Recent antibiotic use
- Weight loss

Studies have demonstrated the alteration in commensal flora present in IBS in both colonic biopsy samples¹³² and stool analysis.¹³³ There is considerable research on optimal methodology for evaluating gut flora. Dysbiosis can be measured by stool analysis and culture, but 99% of colonic flora are facultative anaerobes and only ~50% will be picked up by culture methods. Alterations in the distribution of metabolic by-products of bacterial fermentation, including n-butyrate, propionate, and acetate, can provide a proxy for the distribution of colonic flora. Decrease or absence of normal *Lactobacillus*, *Bifidobacter*, and *E. coli* species in stool culture is an indication of imbalance.¹³⁴

Recent studies on the pathogenesis of IBS have evaluated the common association with small bowel bacterial overgrowth (SBBO), also known as bacterial overgrowth of the small intestine (BOSI) and small intestinal bacterial overgrowth (SIBO). SBBO is noted when the coliform and anaerobic bacteria from the large intestine produce deleterious effects within the delicate environment of the small intestine. A simple breath test is performed by measuring hydrogen and methane gas produced after oral administration of lactulose. As gut bacteria ferment the lactulose, the gas production increases. Typically, the gas production will increase when the fermentable substrate has passed into the large intestine, but patients with SBBO have this increase in gas production much earlier. Intestinal dysbiosis has been noted to be present in 78% of IBS patients who tested positive for SBBO. When treated with antibiotic therapy, 48% of patients no longer met the Rome Criteria for IBS.¹³⁵ Studies have recently begun to evaluate probiotic therapy to improve the rate of SBBO, but results are not yet available.

It is well recognized that several other chronic diseases have a high degree of overlap with IBS, including fibromyalgia, interstitial cystitis, and chronic fatigue syndrome.¹³⁶ Studies in patients with fibromyalgia have shown that 100%¹³⁷ and 77%¹³⁸ of patients also have SBBO. It has been postulated that the immune response to bacterial antigens present in the small intestine provides a framework for understanding the hypersensitivity present in both IBS and fibromyalgia.¹³⁹ Thus, we begin to see that alteration in the distribution of gut flora is associated with clinical syndromes outside of the gastrointestinal tract. It is useful and important to modulate the gut flora for improved health by supplement-

ing the diet with prebiotics and probiotics. Assessment of the overall microbiota community with stool culture allows for initial evaluation and the opportunity for evaluating treatment efficacy.

The word *probiotic* (derived from the Greek and meaning “for life”) was first used in 1965 to describe a function that is opposite to that of antibiotics. It has subsequently been defined as “a preparation of or a product containing viable, defined microorganisms in sufficient numbers, which alter the microflora (by implantation or colonization) in a compartment of the host and by that exert beneficial health effects on the host.”¹⁴⁰ A probiotic must be of human origin, be non-pathogenic in nature, be resistant to destruction by gastric acid and bile, adhere to intestinal epithelial tissue, and be able to colonize the gastrointestinal tract (if only for a short period).¹⁴¹ Other common desirable properties include being able to produce antimicrobial substances, modulate immune responses, and influence human metabolic activities.

A prebiotic has been defined as “a non-digestible food ingredient which beneficially affects the host by selectively stimulating the growth of and/or activating the metabolism of one (or more) health-promoting bacteria in the intestinal tract, thus improving the host’s intestinal balance.”¹⁴² Prebiotics induce antimicrobial effects via their selective stimulation of commensal strains that modulate immune function and compete with pathogens for receptors. Specific prebiotics are now being developed to help promote the growth of beneficial bacteria and selected probiotics.¹⁴³ Combinations of prebiotics and probiotics are collectively known as synbiotics.

The most common probiotic bacteria are:

- *Bifidobacterium*—25% of adult colonic bacteria and 95% of a breastfed newborn;
- *Lactobacillus*—several beneficial strains (GG, NCFM, acidophilus) have been identified;
- *Saccharomyces boulardii*—a patented yeast product that inhibits growth of pathogens.

Probiotic supplementation has been shown to be beneficial in antibiotic-associated diarrhea, necrotizing enterocolitis (NEC),¹⁴⁴ cancer prevention,¹⁴⁵ health promotion,¹⁴⁶ and *H. pylori* prevention.¹⁴⁷ Recently, researchers have also demonstrated the beneficial

effect of probiotics for improving symptoms in IBS,¹⁴⁸ and for normalizing imbalances with inflammatory cytokine ratios.¹⁴⁹ Probiotics are moving into the mainstream of treatment options for IBS, as well as IBD.¹⁵⁰ Disease-specific activity and modulation of the immune system are bacterial species- and subspecies-dependent processes. Thus, the overall community of bacterial flora becomes a critical determining factor for promoting health and preventing/treating disease.

As the human host is highly adaptive to the presence of commensal bacteria, there is a dynamic learning opportunity that continues to unfold as probiotics and prebiotics are utilized therapeutically and preventively. What is the optimal endpoint for treatment? New quantitative molecular techniques with 16S ribosomal RNA probes are now being developed to characterize and quantify the 400+ bacterial families present within the colonic environment.¹⁵¹ Questions abound regarding what constitutes optimal flora. This is an important limitation for treatment planning and health-promotion efforts. In the future, nutritional interventions may target probiotic strains based upon their specific characteristics to activate an inhibitory mucosal response. Until that time, phenotypic markers of digestion, absorption, inflammation, and dysbiosis will help clarify the patient’s progress.

In addition to the benefit of probiotic therapies in IBS and IBD, additional studies have successfully used probiotics as a preventive strategy for infants at risk for atopic illness. Based upon the immunologic imbalance of T-helper cells offered in the hygiene hypothesis, researchers in Finland gave probiotics to infants with a family history of atopic illness and demonstrated a 50% reduction in incidence.¹⁵² A follow-up study at four years confirmed these findings.¹⁵³ Isolauri and her colleagues showed that the anti-allergenic and anti-inflammatory activity of supplemental probiotics was mediated, at least in part, by a decrease in intestinal permeability.¹⁵⁴ These findings have been confirmed in children with moderate to severe atopic dermatitis, with the improvement in intestinal permeability correlating with improvements in the severity of eczema.¹⁵⁵

Hygiene Hypothesis Reconsidered

Recent analyses have questioned the primacy of Th1/Th2 imbalance in the presence of both allergic (Th2) and autoimmune (Th1) diseases. Mammalian evolution has kept us in close contact with relatively harmless microorganisms over a very long period of time. In fact, it is clear that our innate immune system has evolved to recognize these old friends as harmless. However, in affluent countries, we may not have the necessary “friends” present to consistently stimulate the maturation of regulatory T cells (T_{reg})—the heart of the hygiene hypothesis. Thus, immunoregulation as determined by the $T_{effector}/T_{reg}$ balance may be a more crucial factor than Th1/Th2 balance.¹⁵⁶

The innate immune system discriminates between potential pathogens and commensal bacteria by using a number of pattern-recognition receptors (PRRs). Mammalian cells express a series of toll-like receptors (TLRs) that recognize bacterial and microbial structures, including DNA.¹⁵⁷ When infection or pathogens are present, the inflammatory response can increase intestinal permeability. This allows for increased sampling of gut flora by the immune system—a physiologic process of checks and balances. In the presence of an alteration of the gut flora, immune dysregulation, or a genetic predisposition, there is a sustained chronic inflammation and release of calprotectin from neutrophils.¹⁵⁸ Conversely, the presence of healthy commensal flora and/or probiotics has been shown to have an anti-inflammatory effect on the gastrointestinal epithelium.¹⁵⁹

Mucosal Integrity

Significant permeability changes in the gut mucosa can have profound effects on anatomic and immunologic barriers to disease.¹⁶⁰ Intestinal hyperpermeability, also known as leaky gut, can lead to increased inflammatory cytokine production and a propagation of inflammation within the intestine.¹⁶¹ There is a great deal of evidence linking increased intestinal permeability with multiorgan system failure, systemic disease, and immune dysfunction.¹⁶² Animal models also demonstrate that stress significantly increases intestinal permeability.¹⁶³ Studies have focused on animal models and the results are now being brought to bear on cases of trauma and sepsis.¹⁶⁴ Studies on ischemia and reperfusion injury have confirmed a disturbed intestinal barrier¹⁶⁵ and increases in intestinal permeability correlate with multiple organ failure.¹⁶⁶

The assessment of intestinal permeability is performed with a standardized double sugar test. The patient drinks a mixture of lactulose and mannitol. The larger lactulose molecule is only minimally absorbed (in the healthy patient) and the smaller mannitol molecule is absorbed through the microvilli of the duodenum and jejunum. Absorbed sugars are then excreted through the urine and measured individually. The relative ratio of urinary lactulose/mannitol is used as the determinant of increased permeability. Decreased levels of mannitol are indicative of poor absorption and may be an indication of microvilli damage.

While some have questioned the more simplistic model of leaky gut, the gastroenterology literature has validated the value of the double sugar test in studies using histology and electron microscopy.¹⁶⁷ Studies have demonstrated that the bacterial translocation across the gastrointestinal epithelium induces antibodies to bacterial components with antigenic cross-reactivity to HLA antigens.¹⁶⁸ *Klebsiella* has been associated with ankylosing spondylitis when cross-reactivity occurs with the HLA-B27 antigen.¹⁶⁹ Similarly, *Proteus mirabilis* has been associated with reactive arthritis and is known to cross-react with the HLA-DR4 antigen.¹⁷⁰ There is currently anecdotal evidence that the modification of gastrointestinal flora with antibiotics can have an effect on these arthritides, although formal studies to confirm or deny this relationship are not currently available.

It has also been observed that a number of inflammatory conditions, such as asthma, eczema, psoriasis, and Crohn's disease, all affect the epithelial surfaces. Alterations in barrier defense and epithelial permeability are present in each of these diseases.¹⁷¹ Further clinical studies have demonstrated that there is an increase in intestinal permeability in asthma, suggesting that the entire mucosal immune system is affected.¹⁷² Intervention trials have not been reported, but anecdotal data from researchers and naturopathic physicians have suggested that there is a subset of asthmatic and atopic patients (~10–20%) who improve with treatments to decrease intestinal permeability.

The first approach to decreasing intestinal permeability is to effectively remove any inflammatory stimuli from the mucosal surface of the intestine. This entails an understanding of tools to assess digestive function, as well as the diagnostic tools that can be utilized to identify/quantify the degree of intestinal permeability. Sources of inflammation and increased intestinal perme-

ability include infections and pathogens (including *Candida*), altered commensal flora (i.e., dysbiosis), celiac disease, lactose intolerance, and food allergies. Once the implicated agent has been effectively removed, clinical symptoms often begin to improve within 3–5 days, the turnover time of the intestinal epithelium.

Therapeutic agents include probiotics—to utilize their anti-inflammatory nature—along with the cultivation of appropriate metabolic substrates to assist in the differentiation of the epithelial lining. After removing the source of initial injury and inflammation, glutamine is one of the most powerful agents used to supply energy to enterocytes and colonocytes.¹⁷³ L-glutamine is a very useful clinical tool, but it is also a substrate for lymphocytes and macrophages, in addition to being a precursor of nitric oxide. Thus, it is necessary to ensure that inflammation is resolved before treating with this powerful trophic factor. Glutamine has also been noted to be a substrate for *Candida* synthesis, so this should be evaluated before initiating therapy.

Mucosal Immune System

As has been noted, the intestine is the primary immune organ in the body, containing nearly 70% of the immune cells—more than 10^6 lymphocytes/g of tissue.¹⁷⁴ The gut-associated lymphoid tissue (GALT) represents the largest mass of immunocompetent cells within the human body. The regulatory function occurs in several areas—e.g., the more organized Peyer's patches and the diffusely distributed intra-epithelial lymphocytes (IELs). These critical components of the innate immune system sample the luminal contents of the gastrointestinal tract, coordinate host responses, and synthesize inflammatory mediators as they differentiate between potential pathogens and commensal bacteria. Much of this process is mediated by the recently discovered toll-like receptors (TLRs), a sub-set of pattern recognition receptors that recognize different bacterial components and quickly respond with differential stimulation of the adaptive immune response.

The dialogue between host and bacteria at the mucosal interface plays an important part in the development of a competent immune system. Microbial colonization of the gastrointestinal tract affects the composition of the GALT. Many diverse interactions between microbes, epithelium, and gut-associated lymphoid tissue are involved in creating the memory of the

immune system. For instance, commensal flora are intimately involved in the development of oral tolerance, part of the body's acceptance of something as self.¹⁷⁵ The ability to recognize food particles and commensal bacteria is critical for educating the adaptive immune system properly.

Immunologic Cross-Talk

Inflammatory bowel disease (IBD) is an important example we can use to understand how to evaluate imbalance within the mucosal immune system. Three factors are required for abnormal physiology to evolve into inflammatory bowel disease: altered intestinal permeability, access of gut contents to immunologic cells within the GALT and the MALT (mucosa-associated lymphoid tissue), and an abnormal immune response. Alterations in mucosal integrity that do not include an abnormal immune response will also tend to cause dysfunction within the system, though in a much more subtle manner. Luminal contents that can have a stimulatory effect on the immune system include bacteria, bacterial antigens, food antigens, and toxins. Translocation of bacteria can stimulate a physiologically normal inflammatory response when function is healthy and balanced.¹⁷⁶ When a significant number of pathogenic bacteria translocate across the epithelial lining, there is an overt inflammatory response from the gut-associated lymphoid tissue. The upregulation of inflammatory cytokines provides the body with a rapid response to invasion (see Chapter 23). Multiple mechanisms of cross-talk between the bacteria and epithelia that differentiate between the process of recognition and oral tolerance vs. effectively responding to pathogenic bacteria have been described.¹⁷⁷

Oral Tolerance

Oral tolerance has been defined as the immunologic hypo-responsiveness to an antigen encountered through the enteric route, usually through oral administration.¹⁷⁸ The mucosal immune system is able to tolerate an abundance of dietary antigens and commensal bacteria, while still effectively repelling pathogens. Desensitization methods have been used to deal with allergic reactions, including food allergies, since the 1960s. Studies have been done in humans that apply the principles of oral tolerance to autoimmune and allergic diseases. In at least one such study, ~80% of patients with food

allergies were desensitized to increasing doses over time,¹⁷⁹ however, treatments for autoimmune diseases such as IDDM, multiple sclerosis, and Reiter's syndrome have been less effective. Several trials with rheumatoid arthritis were effective, with therapeutic responses to oral collagen challenge.¹⁸⁰ The reason for this therapeutic effect is not clear, though it has been postulated that the source of initial antigen exposure may also be oral. Animal studies also seem to indicate that the relationship of maternal fatty acid ingestion during pregnancy may influence the induction of neonatal immunological tolerance. This means that mothers who had increased n-6/n-3 fatty acid ratios while pregnant had offspring with an increased prevalence of allergy.¹⁸¹

Different bacteria induce different immunologic responses. Nonpathogenic bacteria also elicit different cytokine responses from epithelial cells, inducing differential effects on the GALT and the adaptive immune system.¹⁸² We can see from this dynamic interplay between the gut flora and the GALT that the immunologic response system can be modified, based upon dietary changes (in the form of prebiotics) and beneficial bacteria (in the form of probiotics).

One of the factors noted in the degree of immune response is the adhesion capacity of antigens to epithelial cells.¹⁸³ Strong adhesion of antigens to the epithelial cells is seen with increased immune response. Now it is seen that IBD patients are not tolerant of their own gut flora¹⁸⁴ but, interestingly, the administration of fecal flora derived from healthy controls has been shown to be effective.¹⁸⁵ A continuum of symptoms from IBS to IBD has been proposed¹⁸⁶ that includes alterations in gut flora, immune dysregulation and inflammation, altered mucosal permeability, and stress-induced symptoms. Epidemiologic evidence seems to bear out that some of the rapid increase in IBD may be due to large numbers of IBS patients, and the continuously increased risk of IBD detection in IBS patients favors a true association between the two.¹⁸⁷

Food Allergies

These data indicate that commensal flora may play a paradoxical role in immune regulation, depending upon the antigen, intestinal permeability, degree of inflammation, and maturation of the GALT. This phenomenon is particularly important in early infancy. The intestinal barrier is more permeable with a physiologic inflammation present, as noted by elevated fecal calprotectin lev-

els over the first six to 12 months of life. The cytokine profile is polarized toward humoral immunity (antibody production) and away from cell-mediated immunity.

This immunologic imbalance sets up the situation in which the immature gut is much more sensitive to oral antigens and food allergy. It is clear that allergic reactions to food are much more common in the first few years of life.¹⁸⁸ It has been postulated that the increased prevalence of formula feeding and subsequent loss of the critical immunologic factors present in breast milk have contributed to the increase in the incidence of immune-based disorders, such as allergy and asthma.¹⁸⁹ The studies by Isolauri et al. discussed earlier strongly support this hypothesis, as the prebiotic effect of breast milk encourages the growth of bifidobacteria and leads to significant differences in gastrointestinal flora at six months of age.¹⁹⁰

The environmental setting of low-grade inflammation and increased mucosal permeability induces changes in antigen handling that lead to sensitization. This implies that allergic response to dietary antigens is caused by a failure of the GALT to maintain oral tolerance to these antigens.¹⁹¹ It would follow that the role of probiotics in the treatment of food allergies in adults would be of benefit.¹⁹² In general, the clinical approach to working with food allergies is to evaluate the client with an elimination/challenge diet (described briefly in the first part of this chapter and more extensively in Chapter 35). The removal of an antigen that is recognized as foreign for 21 to 28 days should improve symptoms, but it is necessary that all offending antigens be removed. Thus, a modified elimination diet may not have the requisite restrictions to be effective.

After removal of potentially offending food antigens for three to four weeks (the time period may be increased up to several months if needed), the patient carefully adds back a new food once every few days; frequency recommendations vary, but 2–4 days between foods is a common range for the reintroduction process. This time frame allows for recognition of delayed hypersensitivity responses. This methodical process is usually limited to the most common food allergens, including cow's milk, wheat, egg, corn, soy, and tree nuts; however, it can be adapted to eliminate and challenge any suspicious foods. This elimination/challenge process is the gold standard of allergy testing. No commercially available allergy tests, regardless of methodology, are as accurate. Patients are strongly encouraged to

follow through with the elimination/challenge diet, but it is imperative that the clinician help the patient to embrace the process with adequate preparation and a positive attitude.

Considering the diversity of immunologic pathways, it is clear that using a single entity (such as serum IgG levels) to measure food allergies would be incomplete.¹⁹³ Functional assays to measure lymphocyte stimulation have not demonstrated good reproducibility. A recent study did demonstrate clinical utility in the utilization of IgG levels as a diagnostic tool to determine a modified elimination diet in patients with IBS. In comparison with a group receiving a sham diet, the patients whose diets were based upon eliminating foods with IgG reactivity were 30% improved.¹⁹⁴ In her commentary on this study, Isolauri notes the profound impact of low-grade inflammation and altered mucosal integrity on antigen transfer and the development of allergies: "A healthy gut microbiota is thus an indispensable component of gut barrier function."¹⁹⁵

Once again, probiotics may have a therapeutic role in the case of food allergies. Bacteria produce a number of enzymes and products to assist with the metabolism of food. For example, *Lactobacillus rhamnosus* GG was able to hydrolyze casein and reduce the production of IL-4 in atopic infants with cow's milk allergy.¹⁹⁶ Probiotics modify the structure of potentially harmful antigens and lower their potential for harm. Current studies are now underway to evaluate the feasibility of creating a group of probiotic bacteria with the capacity to break down gluten in such a manner that people diagnosed with celiac disease will still be able to eat wheat products.¹⁹⁷

Commensal bacteria have effects that extend across a range of immunologic imbalance. We have discussed the importance of commensal flora on stabilizing gut flora, promoting the integrity of the intestinal barrier, supporting host resistance to pathogenic bacteria, and modulating immune response. All of these qualities extend to the therapeutic use of probiotics. The anti-inflammatory and immunomodulatory effects of probiotics provide the basis for therapeutic intervention. Beneficial effects have been demonstrated in IBD,¹⁹⁸ IBS,¹⁹⁹ atopic illness,²⁰⁰ and food allergies.²⁰¹

Stool Analysis

Evaluating the effectiveness of probiotics in normalizing the gut flora may not be as simple as measuring the change in bacterial counts in stool culture at the

species level, although these are the best clinical tools that we have right now. Microbial analysis of stool samples provides clinical insight into the flora population of the distal colon. Quantitative growth on the agar plate reflects the levels of bacteria in the distal colon. Results obtained from fecal samples demonstrate that 50–80% of total microscopic composition is recovered by fecal culture. There is good agreement on the degree of biodiversity when fecal cultures are compared with 16S rDNA sequence analysis.²⁰²

The predominant beneficial bacteria in the large intestine are Bifidobacteria, strict anaerobes that constitute as much as 25% of the overall colonic flora in healthy adults. In the colon, obligate anaerobes such as Bifidobacteria predominate over facultative anaerobes such as Lactobacilli by 1000:1. Recovery of these organisms in stool culture should therefore ideally be in the 3+ or 4+ ranges. Lactobacilli, facultative anaerobes, have culture growth at 1+ or 2+ in healthy adults. Non-pathogenic *E. coli* populate the distal colon, although they are usually found in reduced quantities, comparable to levels of Lactobacilli. A growth of non-pathogenic *E. coli* from 1+ to 2+ is therefore considered normal.²⁰³

To date, it has been assumed (though not confirmed) that probiotics adhere to the gastrointestinal mucosa.²⁰⁴ Only *in vitro* studies have been able to detect the presence of adhesive substances from probiotics and demonstrate adherence to tissue cells.²⁰⁵ It is clear that probiotics exert a number of beneficial effects; however, effects from supplementation may occur from transient passage through the GI tract rather than actual colonization. Studies have shown that 3–14 days after exogenous supplementation ceases probiotics are no longer recovered from the stool.²⁰⁶ It is therefore doubtful in the absence of supplementation that beneficial bacteria will be recovered unless they are of indigenous origin.²⁰⁷ One can assess levels of beneficial bacteria when taking probiotics to ensure that they are delivered to the colon and thus are able to exert their beneficial effects on the host. Alternatively, one can reevaluate the stool microbiology on a patient who has been treated for dysbiosis to ensure that the imbalance in stool flora has been corrected.

Probiotic Treatment

Probiotic dosage will vary based upon the indication for treatment (and/or prevention) and the age of the patient. Strain-specific effects are just beginning to be

published and efficacy data on one sub-species or strain may not be applicable to another, even within the same species. Current data suggest that the intestinal flora in IBD is not normal, even as we strive to better understand the exact nature of the term “normal flora.”²⁰⁸ Epidemiologic data support the idea that insufficient protective commensal flora may impair immune system homeostasis.²⁰⁹ Intervention studies are beginning to prove this therapeutic approach. Studies have demonstrated efficacy for maintenance treatment of pouchitis using 450 billion colony-forming units (cfu) per day.²¹⁰ Much higher doses are currently being studied for treatment of IBD.²¹¹ Additional trials have demonstrated efficacy as adjunctive²¹² and primary therapy²¹³ for ulcerative colitis, using doses of 10–75 billion cfu/day.

Treatment of IBS with probiotics has also been shown to be efficacious in six of eight trials, with response depending upon dosage and strain of probiotic used.²¹⁴ Several studies of IBS treatment with probiotics have utilized doses of 25–75 billion cfu/day of lactobacillus and bifidobacter, demonstrating decrease in flatus and improvement in quality-of-life symptom scores.^{215,216,217} Post-antibiotic therapies have been recommended at 20–25 billion cfu/day to help normalize commensal flora.²¹⁸ Treatment is usually for 3–4 weeks and can begin during antibiotic treatment, as long as it is not taken concomitantly. Benefit in reducing antibiotic-associated diarrhea has also been demonstrated.²¹⁹

In addition to studies on strain-specific effects, studies are needed to evaluate the appropriate dosages for various conditions. It has been assumed empirically that higher dosages may be effective for treatment of disease, and lower dosages are useful for health promotion and disease prevention. A meta-analysis of the utility of Lactobacillus in childhood diarrhea demonstrated its efficacy in reducing diarrhea an average of 0.7 days, with a reduction of bowel movements by 1.6/day on Day 2. A further evaluation of dose response was performed, demonstrating that the reduction in diarrheal days was directly correlated with dosages above 10 billion (10^{10}) cfu and up to 150 billion (10^{11}) cfu per day.²²⁰ Synbiotics (the combination of prebiotics and probiotics) seem to be effective at lower dosages.²²¹

A recent review summarizes the evidence that the immunostimulatory effect of probiotics extends far beyond the gastrointestinal tract to distant mucosal surfaces, including the respiratory and genito-urinary systems.²²² Further research has shown that probiotics

enhance cell-mediated immunity in elderly patients, particularly in people whose immune systems showed poor response before treatment.²²³

Probiotics are extremely safe, even at high doses.²²⁴ No pathogenic or virulence properties have been identified for Lactobacilli or Bifidobacteria.²²⁵ To date, there are no documented cases of septicemia associated with Bifidobacteria. While Lactobacillus has been associated with bacteremia, it has only been documented in severely immunocompromised patients, with prolonged hospitalization and after surgery.²²⁶ Data from Finland do not demonstrate any increase in bacteremia over the past 10 years of rapidly increasing probiotic consumption.²²⁷

Prebiotic Treatment

Fructooligosaccharides (FOS) may act as a fermentative substrate. Because they particularly favor the Bifidobacteria population in the gut, regular ingestion can help these organisms become predominant. A dose of 4 g/day appears sufficient to have this effect *in vivo*.²²⁸ Even at a dose five times higher (i.e., 20 g/d), there is a negligible amount of intact FOS found in the stool, indicating that FOS have been nearly completely fermented in the colon.²²⁹

Summary

It is clear that there is a dynamic relationship involving the gastrointestinal flora, environmental inputs (food and other nutrients), and the health of the immune system. Recent research has taught us a great deal about the role of diet and commensal bacteria in promoting health. It appears that Nobel-laureate Eli Metchnikov may have been correct in his assertion that live bacterial cultures are “the elixir of life.” We are unlocking a number of secrets about immune system functioning, but we keep coming back to a simple intervention that has an ever-expanding opus of research to support it, and an extremely low toxicity ratio.

Future studies will help us to clarify the best strains and the best dosages for individual patients and specific conditions. Assessment of commensal flora and a genomic scan for markers of immunologic dysregulation will be more accurate and more widely available. It appears, however, that the diagnostic and therapeutic tools we have to work with today can make a tremendous difference in reducing the burden of suffering for our patients. If “form follows function,” as Buckminster

Fuller was fond of saying, then the form of our immune system may be following the precise functions that our commensal flora is dictating.

We have the opportunity to encourage breastfeeding, decrease unnecessary antibiotic and antimicrobial usage (especially in the first two years of life), improve oral tolerance with a healthy n-6/n-3 fatty acid ratio, and support the development of a healthy commensal flora. These actions on behalf of our immune systems will pay dividends for years to come.

The Enteric Nervous System

Michael D. Gershon, MD¹

The Enteric Nervous System is Independent

The behavior of scientists and lemmings can sometimes have more in common than the scientists would like to admit. The actions of isolated lemmings are rarely exceptional; however, when they form a herd, lemmings have been known to stampede and follow the mass of their colleagues off a cliff. The actions of isolated scientists are also unexceptional and dictated by the scientific method, but like lemmings, scientists can abandon rational thought and follow their colleagues into the mass acceptance of a mistake. The history of the enteric nervous system (ENS) is a good example of the lemming approach to scientific thought. The idea that the gut contains an intrinsic nervous system (the ENS) that can, when it is called upon to do so, control the behavior of the bowel is old enough to have celebrated the beginnings of two new centuries.^{230,231,232} The concept of intrinsic enteric neuronal control of gastrointestinal activity dates from the formulation of the “law of the intestine” by Bayliss and Starling as the 19th century came to a close. This “law” holds that increases in intraluminal pressure result in oral contraction and anal relaxation of the gut that persists in the face of ablation of the entire extrinsic innervation of the bowel. Bayliss and Starling attributed the “law of the intestine” to the “local nervous mechanism” (the ENS) of the gut, which had previously been shown by Auer-

bach (the myenteric plexus)^{233,234} and Meissner (the submucosal plexus)²³⁵ to be very large.

The “law of the intestine” is now called the peristaltic reflex and does not require the presence of the brain, spinal cord, dorsal root, or cranial nerve ganglia for its manifestation. Trendelenburg clearly demonstrated, while World War I raged in Europe, that the peristaltic reflex can be evoked in loops of guinea pig small intestine isolated *in vitro*.²³⁶ In 1921, Langley established the ENS as a separate but equal division of the autonomic nervous system, which he defined.²³⁷ Parasympathetic nerves were classified as those with cranial and sacral preganglionic connections to the central nervous system (CNS), while sympathetic nerves were those with thoracic and lumbar connections. Because Langley believed that the CNS did not directly innervate most enteric neurons, these neurons were grouped into their own autonomic division, called the ENS. After Langley, the lemming effect eclipsed the ENS, and it was almost universally dismissed as a collection of parasympathetic relay ganglia in the wall of the bowel. This eclipse has now blessedly ended and research on the ENS has effectively resumed, to the great practical benefit of clinical medicine.^{238,239,240,241}

The ENS is Structurally and Chemically Similar to the CNS

The ENS has many unique organizational features. It lacks internal collagen, and enteric neurons are supported, not by Schwann cells, as in the remainder of the peripheral nervous system, but by enteric glia.^{242,243,244,245,246} The small intestine contains at least as many neurons (>10⁸ in humans) as the spinal cord,^{247,248} and these neurons exhibit a phenotypic diversity that is unparalleled in other peripheral ganglia. By now, every class of CNS neurotransmitter has also been found in the ENS.^{249,250} The ENS thus resembles the brain, and is, like the brain, too complex to be easily understood. Much of this complexity is manifested in microcircuits that are notoriously difficult to define.²⁵¹ Progress, however, has been made, and the rate has recently been accelerating.

Neuronal Detection of Intraluminal Conditions is Transepithelial

In order for the ENS to regulate the behaviors of the bowel, it is obviously necessary for it to be apprised of conditions (pressure, pH, nutrient concentrations, etc.) prevailing in the enteric lumen; nevertheless, nerve fibers do not enter the gastrointestinal lumen or even its epithelial lining. Sensation must therefore be accomplished transepithelially.^{252,253,254} The ability of enteroendocrine cells to act as sensory transducers helps to make this possible. Enterochromaffin (EC) cells are the best characterized of these transducer cells.^{255,256,257} Prodigious quantities of serotonin (5-hydroxytryptamine; 5-HT) are stored in EC cells. The bowel contains about 95% of the body's serotonin and EC cells contain most of that 5-HT. What 5-HT is present in the gut that is not in EC cells is in the ENS, the myenteric plexus of which contains descending serotonergic interneurons.^{258,259} Two isoforms of tryptophan hydroxylase (TpH1 and TpH2) have been identified.²⁶⁰ Because of the presence of EC cells, the mucosa contains TpH1 and enteric neurons, like their counterparts in the CNS, contain TpH2.^{261,262} The 5-HT storage granules of EC cells are distinctly basolateral in their intracellular distribution.²⁶³ This distribution means that serotonin is primarily secreted from the basolateral surface of EC cells into the lamina propria (Figure 28.2). Here, the secreted 5-HT has access to nerve fibers.^{264,265,266} The constitutive and stimulated secretion of 5-HT into the gut wall by EC cells has recently been confirmed in real time by means of electrochemical detection with small carbon electrodes.²⁶⁷ EC cells constitutively secrete a great deal of 5-HT and even more in response to stimulation. 5-HT thus overflows into the portal circulation and intestinal lumen and this overflow increases postprandially.^{268,269,270,271,272,273,274,275} The copious amounts of 5-HT that EC cells secrete may be necessitated by the large and variable distance that separates EC cells from the nerves that respond to them.²⁷⁶ The enteric epithelium is constantly in the process of replacement; stem cells in intestinal crypts and gastric glands generate new cells, while old cells slough into the lumen. Nerves are not specialized to synapse with moving targets, and epithelial cells move from stem cell to sloughing zones. A paracrine method of 5-HT secretion thus has to suffice, in which specificity is determined by the ligand-receptor relationship, rather than by the anatomy. The large

quantity of secreted 5-HT assures that a sufficient concentration reaches neural receptors. The mechanism is analogous to Niagara Falls. Because a great deal of water flows over Niagara, all boats in the vicinity of the Falls get wet. This type of signaling requires an efficient mechanism to remove 5-HT from the extracellular space. Signaling has to be terminated and 5-HT must be removed from contact with receptors, lest they desensitize. 5-HT is also toxic;²⁷⁷ therefore, its overflow must be kept within tolerable limits.

Figure 28.2 Release of 5-HT from EC cells

Pressure or other stimuli release 5-HT from EC cells. The primary direction of 5-HT secretion (arrows) is into the lamina propria.

SERT-Mediated Uptake Terminates Responses to 5-HT

In contrast to acetylcholine (ACh), which is catabolized by extracellular acetylcholinesterase, there are no extracellular enzymes that catabolize 5-HT. Reuptake is therefore required to terminate responses to 5-HT.^{278,279} Diffusion of 5-HT away from its sites of action is too slow to prevent excessive potentiation of responses and eventual receptor desensitization. 5-HT, moreover, carries a charge at physiologic pH and thus will not cross the lipid bilayer of a plasma membrane. A specific sero-

tonin reuptake transporter (SERT) is present in the plasma membranes of serotonergic neurons,^{280,281,282} which mediates the transmembrane transport of 5-HT. The enteric mucosa, however, lacks a serotonergic innervation. Instead of nerves, therefore, other cells of the gastrointestinal mucosa must undertake the uptake of 5-HT (Figure 28.3). These cells appear to be enterocytes, which in mice, rats, guinea pigs, and humans have all been found to express SERT.^{283,284,285,286} Mucosal and neuronal SERT are identical. Enterocytes probably catabolize the 5-HT after they take it up, not only by oxidative deamination catalyzed by monoamine oxidase, as in the brain, but also by O-glucuronidation.^{287,288}

Figure 28.3 5-HT is taken up by enterocytes

Following its action in the lamina propria, 5-HT is taken up by enterocytes (gray arrows). This uptake terminates serotonergic signaling and thus prevents excessive stimulation of receptors and receptor desensitization.

Tricyclic antidepressants, serotonin selective reuptake inhibitors, and cocaine inhibit SERT.²⁸⁹ These compounds all exert gastrointestinal effects,^{290,291,292} but these actions are prevented from being catastrophic by the enteric expression of other transporters that can substitute for SERT; these molecules catalyze the uptake of 5-HT with a lower affinity than that of SERT, but they have a high capacity.²⁹³ Backup transporters include organic cation transporters, the distributions of which

resemble that of SERT, and the dopamine transporter, which is located in enteric dopaminergic neurons.²⁹⁴

The basic serotonergic signaling unit of the mucosa thus consists of EC cells as the sensory transducers, 5-HT as the first messenger of sensory transduction, 5-HT receptor-expressing processes of intrinsic and extrinsic primary afferent nerves in the lamina propria as the receptive elements, and SERT-expressing enterocytes as the signal terminators.

Intrinsic Primary Afferent Neurons Enable the ENS to Mediate Reflexes Independently of CNS Input

The brain requires peripheral sensors to regulate behavior. Information from these sensors, of course, is transmitted to the CNS by means of dorsal root and cranial nerve ganglion cells. An analogous system operates in the gut. Independence from the CNS requires that the ENS be able to respond to sensors that detect luminal stimuli, and this ability, in turn, depends on the presence of intrinsic primary afferent neurons (IPANs), which are to the bowel what dorsal root and cranial nerve ganglion neurons are to the CNS. IPANs transmit information from sensors, such as EC cells, to the processing neurons of the ganglionated enteric plexuses (Figure 28.4). Both submucosal and myenteric IPANs have been described.^{295,296,297,298} Mucosally-driven peristaltic and secretory reflexes appear to critically depend on submucosal IPANs.^{299,300,301} Stretch-driven reflexes^{302,303} and giant migrating contractions, which are ultrapropulsive,³⁰⁴ may be mediated by myenteric IPANs. Both submucosal and myenteric IPANs are cholinergic in rodents^{305,306,307} and humans.³⁰⁸ Interestingly, myenteric IPANs display a characteristic bursting pattern of activity (about four action potentials per burst) when stimulated via the mucosa.³⁰⁹ The significance of this bursting activity, in terms of the types of motility dependent on myenteric IPANs, has yet to be determined. Submucosal IPANs evidently secrete calcitonin gene-related peptide (CGRP) together with ACh.^{310,311,312} Fast excitatory neurotransmission is cholinergic, while CGRP mediates slow excitatory neurotransmission,³¹³ which increases the excitability of submucosal ganglia. Inhibition of CGRP-mediated slow excitation thus interferes with the circumferential spread of excitation. In the guinea pig bowel, most myenteric IPANs exhibit a Dogiel Type II morphology and contain the calcium-binding protein, calbindin.^{314,315,316} Calbindin, however, does not mark myenteric IPANs in all species.³¹⁷ In

humans, myenteric IPANs have been reported to contain somatostatin, substance P, and another calcium binding protein, calretinin.³¹⁸ Certain differentiation antigens are commonly expressed by IPANs, dorsal root, and cranial nerve sensory ganglion cells,³¹⁹ nevertheless, submucosal and myenteric IPANs differ from dorsal root and cranial nerve sensory ganglion neurons in that IPANs are innervated, while dorsal root and cranial nerve sensory ganglion neurons are not; IPANs may thus be dual function cells, able to act as interneurons as well as initiators of enteric reflexes.^{320,321,322,323,324}

Figure 28.4 5-HT secreted by EC cells activates IPANS

5-HT secreted by EC cells activates intrinsic primary afferent neurons (IPANs) of the submucosal plexus. These cells, which are analogous in function to sensory neurons of dorsal root and cranial nerve ganglia, initiate peristaltic and secretory reflexes. The receptor activity that mediates stimulation of these cells by 5-HT is called 5-HT_{1P}. Neither 5-HT₃ nor 5-HT₄ receptors activate submucosal IPANs; thus, neither of these receptors, by themselves, initiates peristaltic or secretory reflexes.

5-HT_{1P} Receptor Activity Stimulates Submucosal IPANs

The submucosal IPANs that initiate peristaltic and secretory reflexes are activated in the mucosa by a uniquely enteric receptor activity, called 5-HT_{1P}.^{325,326,327,328} (Figure 28.4). Because a distinct 5-HT_{1P} receptor has not yet been cloned, it is defined operationally and by its transduction mechanism; the 5-HT_{1P} site is thus referred to here as a “receptor activity.” 5-HT_{1P} receptor activity has not been described in the CNS, although it has been reported to be present in skin and lymphoid tissue as well as the gut.³²⁹ 5-HT_{1P} receptor activity is activated by indoles with an unsubstituted hydroxyl moiety at the 5 or 6 position and is not affected by most conventional 5-HT antagonists. Hydroxylated indalpine derivatives have also been reported to be relatively selective 5-HT_{1P} agonists, while a dipeptide, N-acetyl-5-hydroxytryptophyl-5-hydroxytryptophan amide (5-HTP-DP) and renzapride have been reported to be 5-HT_{1P} antagonists.^{330,331} Renzapride, which is also a 5-HT₄ agonist³³² and a 5-HT₃ antagonist,³³³ is, of course, not at all selective. Submucosal IPANs are activated by mucosal stimulation and 5-HTP-DP blocks this activation.³³⁴ 5-HTP-DP also inhibits the initiation of peristaltic and secretory reflexes.^{335,336,337,338} In addition to its role in activating submucosal IPANs, 5-HT_{1P} activity mediates slow responses of enteric neurons to 5-HT and slow excitatory serotonergic neurotransmission in the ENS.^{339,340,341} It seems likely that drugs that affect 5-HT_{1P} activity would not be good for the regulation of intestinal motility. Because 5-HT_{1P} activity initiates reflexes and activates submucosal IPANs, a 5-HT_{1P} antagonist might induce paralytic ileus by blocking peristaltic and secretory reflexes. Similarly, a 5-HT_{1P} agonist might, by activating submucosal IPANs, lead to severe diarrhea. 5-Hydroxyindalpine, for example, is a 5-HT_{1P} agonist and has been identified as the metabolite of indalpine in a clinical trial that induced unacceptable diarrhea.³⁴² Although drugs that activate IPANs are likely to be prokinetic and compounds that prevent their activation are likely to inhibit motility, neither would probably be useful in therapy. Agents that exhibit either of these effects would be expected to be difficult to control, leading respectively to unacceptable constipation or diarrhea. In contrast, the distal terminals

of IPANs are a more attractive site at which to target a therapeutic agent because drugs that act at this site would strengthen or weaken neurotransmission in enteric microcircuits but would rely on natural stimuli to initiate reflexes.

5-HT₄ Receptors are Presynaptic and Strengthen Neurotransmission in Prokinetic Pathways

The secretion of ACh and CGRP from stimulated submucosal IPANs is increased by 5-HT.^{343,344,345} 5-HT thus potentiates the effects of both of these transmitters and enhances neurotransmission from submucosal IPANs to second order neurons (Figure 28.5). The spread of excitation within the bowel from a point of application of a mucosal stimulus is thus made greater and propulsive peristaltic and secretory reflexes are enhanced. 5-HT₄ receptors mediate the 5-HT-induced increase in ACh and CGRP release from submucosal IPANs. Similarly, 5-HT₄ receptors also increase the secretion of ACh at nerve-nerve synapses in the myenteric plexus,^{346,347} as well as at motor nerve-smooth muscle junctions.³⁴⁸ All of these effects of 5-HT₄ receptor stimulation are prokinetic. Electrophysiologic recordings reveal that 5-HT₄ receptor agonists, such as tegaserod, renzapride, and cisapride, increase the amplitude of fast excitatory postsynaptic potentials (EPSP) or, in patch-clamp recordings, fast excitatory postsynaptic currents in myenteric neurons in response to presynaptic stimulation.^{349,350,351} 5-HT₄ antagonists, such as GR113808, do not affect the EPSPs or ESPCs, which are mediated ACh acting at nicotinic receptors; however, 5-HT₄ antagonists prevent the enhancement of EPSPs or ESPCs elicited by 5-HT or 5-HT₄ agonists. 5-HT₄ agonists do not evoke postsynaptic responses and thus exert no direct effects on enteric neurons. Postsynaptic responses to 5-HT are all mediated by other subtypes of 5-HT receptors. The 5-HT-induced fast depolarization (or fast inward current in patch-clamp recordings) is 5-HT₃ mediated.^{352,353} The 5-HT-evoked slow depolarization (or slow inward current in patch-clamp recordings) is 5-HT_{1P} mediated.^{354,355,356,357} The postsynaptic locations of the 5-HT₃^{358,359} and 5-HT_{1P} receptors,³⁶⁰ determined by immunocytochemistry, are consistent with their pharmacological actions.

Figure 28.5 5HT₄ receptors are presynaptic

5-HT₄ receptors are presynaptic and are found at the terminals of submucosal IPANs, at synapses within the myenteric plexus, and at the neuromuscular junction. 5-HT₄ stimulation enhances the secretion of ACh and CGRP from stimulated nerve endings. The effect of activating 5-HT₄ receptors is to strengthen the neurotransmission in prokinetic pathways.

In contrast to 5-HT₃ and 5-HT_{1P} receptors, enteric plasmalemmal 5-HT₄ receptors are exclusively presynaptic.³⁶¹ Neurons that express 5-HT₄ receptors have been identified by *in situ* hybridization, and the receptor protein has been located with selective antibodies. Rabbit antibodies react with the 5-HT_{4a} isoform,^{362,363} while chicken antibodies appear to recognize all isoforms of the 5-HT₄ receptor (personal observations). Subsets of both submucosal and myenteric neurons express 5-HT₄ as do some of the smooth muscle cells of the muscularis externa. 5-HT₄ immunoreactivity is especially dense in the neuropil at the light microscopic level. At the electron microscopic level, the 5-HT₄-immunoreactive receptor sites are found in the rough endoplasmic reticulum of neurons, the plasma membranes, internal vesicles of neurites (presumably axons), and on the presynaptic membranes of synapses. In contrast to the presynaptic

membranes, the postsynaptic elements are not labeled by antibodies to 5-HT₄ receptors. The location of 5-HT₄ receptors, therefore, corresponds to the responses that have been observed to 5-HT₄ agonists. These compounds promote neurotransmission by enhancing release of excitatory neurotransmitters, and the receptors are located on the presynaptic side of synapses (Figure 28.5). The location of 5-HT₄ receptors and the nature of 5-HT₄ effects undoubtedly contribute to the safety of 5-HT₄ agonists, such as tegaserod, as therapeutic agents. To enhance motility, 5-HT₄ agonists depend on natural stimuli to evoke peristaltic and secretory reflexes. 5-HT₄ agonists thus do not constitutively activate these reflexes. They also do not activate nociceptors to send distress signals to the CNS.

When motility of the gut is inadequate, as in cases of chronic constipation or the constipation-predominant form of the irritable bowel syndrome (IBS-C), tegaserod provides relief and consistently outperforms a placebo in fair double-blind matches.^{364,365,366,367,368,369,370} Unfortunately, if enteric neurons have degenerated, tegaserod cannot restore their function. When a drug acts presynaptically, it can only be of use if the presynaptic elements are present and contain transmitters to be released. Diabetic gastroparesis, therefore, is not likely to be responsive to treatment with tegaserod. Obviously, when motility is normal or excessive, the presynaptic enhancement of neurotransmitter release by tegaserod or a similar agent would be counterproductive. Tegaserod, or another 5-HT₄ agonist, would thus be contraindicated if motility or secretion is already excessive, as in the diarrhea-predominant form of irritable bowel syndrome (IBS-D). Tegaserod's use in IBS is thus restricted to the constipation-predominant form (IBS-C) of the condition.

5-HT₃ Receptors are Involved in Gut-to-Brain Signaling

IBS patients, who tend to focus on their visible symptoms of diarrhea or constipation, often overlook sensation from the bowel and attribute their discomfort to what they see. That leads these individuals to seek symptomatic treatment that fails to provide adequate relief. Overlooked or not, however, sensory reception

from the bowel is an important component of IBS. Pain or discomfort is an integral component of IBS.³⁷¹ Visceral hypersensitivity, indeed, may be the most distressing component of IBS.^{372,373,374} That should not be surprising, since more than 90% of vagal fibers are not centripetal but centrifugal, carrying information from the gut to the brain.^{375,376,377} These sensory fibers, moreover, are supplemented by spinal nerves that transmit nociceptive data. Some of the information sent by the bowel to the brain, however, may not be perceived. Depression and epilepsy can be treated by stimulating the vagi, which also can improve learning and memory.^{378,379,380,381} Natural stimulation of the vagus nerves in the bowel may thus influence the brain and affect mood, improving it when normal and disturbing it when abnormal.

Although the gut can, as noted earlier, function in the absence of CNS input, it does not normally do so. The ENS and the CNS can be thought of as two operators of an alimentary unit that have to work together. For the CNS to make informed decisions and worthwhile contributions to alimentation, it must, like the ENS, be informed about what is happening in the bowel and especially in the enteric lumen. Again, what the brain senses has to be the result of a transepithelial phenomenon because no nerves enter the lumen of the gut, but extrinsic visceral afferent neurons in cranial nerve and dorsal root ganglia, rather than IPANs, signal to the CNS. Instead of the 5-HT_{1P} receptor, which stimulates submucosal IPANs, the 5-HT₃ receptor is responsible for the activation of extrinsic primary neurons^{382,383,384,385} (Figure 28.6). 5-HT₃ receptor immunoreactivity, therefore, is abundant on the enteric processes of extrinsic nerves.^{386,387,388} 5-HT₃ antagonists can thus be used to prevent the activation by 5-HT of visceral afferent nerves in the gut. This action is therapeutically useful, and 5-HT₃ antagonists, such as ondansetron and granisetron, are used to alleviate the nausea and vomiting associated with cancer chemotherapy.^{389,390} Alosetron and cilansetron are effective in counteracting the visceral hypersensitivity associated with IBS-D.^{391,392,393}

Figure 28.6 5-HT₃ receptors are postsynaptic

5-HT₃ receptors are postsynaptic and are a ligand-gated ion channel. They are found on the terminals in the bowel of extrinsic sensory neurons and transmit noxious signals to the CNS. 5-HT₃ receptors are also located on neurons in the myenteric plexus, where they mediate fast excitatory neurotransmission from serotonergic interneurons and on the mucosal terminals of myenteric IPANs. Antagonism of 5-HT₃ receptors interferes with visceral hypersensitivity, but because of the location of 5-HT₃ receptors in the ENS and on myenteric IPANs, 5-HT₃ antagonists may also be constipating.

Importantly, it is the segregation in the gut of 5-HT receptor subtypes, 5-HT_{1P} (Figure 28.4) and 5-HT₄ receptors to the submucosal IPANs (Figure 28.5) that initiate peristaltic and secretory reflexes, and 5-HT₃ to extrinsic visceral afferent nerve endings (Figure 28.6), that makes possible the pharmacologic manipulation of enteric serotonergic signaling. 5-HT₃ antagonists can be given to treat nausea or IBS-D without simultaneously blocking peristaltic or secretory reflexes. 5-HT₄ agonists can be used to enhance motility without simultaneously causing discomfort by stimulating the extrinsic visceral afferent nerve fibers that transmit nociceptive data to the CNS. Myenteric IPANs resemble extrinsic visceral afferent nerve fibers in that their responses to mucosal 5-HT are mediated by 5-HT₃ receptors^{394,395} (Figure 28.6). The failure of 5-HT₃ antagonists to block peristaltic and

secretory reflexes thus indicates that it is the submucosal IPANs, which lack 5-HT₃ receptors and are stimulated only via 5-HT_{1P} receptor activity,³⁹⁶ and not myenteric IPANs that initiate peristaltic and secretory reflexes.

Motility Can Be Slowed by Antagonizing 5-HT₃ Receptors Within the ENS

Extrinsic sensory nerves are not the only neural entities in the gut that express 5-HT₃ receptors (Figure 28.6). Enteric 5-HT₃ receptors are also found on myenteric neurons,^{397,398,399} where they are responsible for serotonergic fast excitatory neurotransmission.^{400,401,402,403} There is evidence that serotonergic interneurons and 5-HT₃ receptors participate in descending excitatory neural pathways.⁴⁰⁴ 5-HT₃ receptors also activate the mucosal terminals of myenteric IPANs.^{405,406} From a therapeutic point of view, the wide distribution of 5-HT₃ receptors is unfortunate. Not only do 5-HT₃ antagonists inhibit the transmission of sensory signals to the CNS by acting on the receptors expressed by extrinsic sensory nerves, they also interfere with serotonergic neurotransmission within the ENS and with the initiation of reflexes by myenteric IPANs. 5-HT₃ antagonism does not prevent the manifestation of peristaltic and secretory reflexes because these reflexes, which are triggered by submucosal IPANs, are activated by other 5-HT_{1P} receptors and strengthened by 5-HT₄ receptors.^{407,408,409} 5-HT₃ antagonists thus do not cause ileus; nevertheless, 5-HT₃ antagonists are constipating.^{410,411,412} Constipation is an annoying side effect of the use of granisetron and ondansetron to alleviate the nausea and vomiting of cancer chemotherapy. It can also be a serious iatrogenic consequence of the misuse of alosetron or cilansetron in IBS. 5-HT₃ antagonists are thus useful in IBS only when the disease is associated with diarrhea. 5-HT₃ antagonists are contraindicated when constipation is a significant element of the condition. When alosetron was the only drug available to treat IBS, it was sometimes misused by physicians who did not understand its limitations and administered it to patients who were already constipated. This led to severe constipation and even rare instances of fecal impaction requiring surgical intervention. Now, however, tegaserod is available to treat IBS-C; tegaserod appears to provide adequate relief, not only

from constipation but also from the consequences of visceral hypersensitivity.^{413,414} The introduction of tegaserod should have made alosetron and cilansetron much safer in practice because the availability of another effective compound specifically for treating constipation should remove the temptation to mistakenly employ alosetron or cilansetron to treat IBS-C. It is not entirely clear how tegaserod relieves discomfort and bloating, because there is no evidence for the expression of 5-HT₄ receptors on extrinsic sensory nerves; conceivably, sensory disturbances from the gut disappear when intestinal motility, compliance, and tone are normalized by tegaserod treatment.

Colonic Motility Is Slowed by the Knockout of 5-HT₄ Receptors

Transgenic mice that lack 5-HT₄ receptors have been generated.⁴¹⁵ These mice show behavioral abnormalities, but they survive to adulthood. As might be expected from the prokinetic action of the 5-HT₄ receptor, colonic motility is abnormally slow in 5-HT₄^{-/-} mice. This observation confirms that the 5-HT₄ receptor not only enhances motility when stimulated pharmacologically, but is also physiologically required for the maintenance of normal colonic motility. Surprisingly, the wall of the colon in some 5-HT₄ knockout mice is thinner than normal. The difference in wall thickness between knockout and normal mice is primarily in the muscularis externa; the thickness of the mucosa is similar in wild-type and 5-HT₄^{-/-} mice. The numbers of neurons in both plexuses are also significantly reduced in older 5-HT₄ knockout animals, although the difference in neuronal numbers is not significant at birth. It is possible that a chronic or prolonged absence of 5-HT₄ receptor stimulation causes neurons and smooth muscle to atrophy in the colon. Alternatively, the poor motility of the colon in 5-HT₄^{-/-} mice might impair the bowel's defense against pathogens, which in turn might exert toxic effects on neurons and muscle. Certainly, an abundance of bacteria can be observed in intestinal crypts in the colon and small intestine in the 5-HT₄^{-/-} mice that is not evident in their wild-type littermates. The data from mice are compatible with the idea that long-standing failure to stimulate 5-HT₄ receptors and/or chronic constipation leads, in at least some animals, to deleterious changes in colonic nerve and muscle. If this is true, then by

analogy to the mice, one wonders whether similar changes occur in human patients with chronic constipation or IBS-C. If so, then it might be important to intervene early with a 5-HT₄ agonist to prevent neuromuscular degeneration in the human intestine. It is impossible to restore 5-HT₄ function in transgenic mice that lack 5-HT₄ receptors; however, it is possible to administer tegaserod to human patients.

Mucosal Expression of SERT Is Decreased in the Bowel in Inflammation and IBS

IBS is defined as a symptom complex.^{416,417} As a result, it is highly likely that all of the patients who carry that diagnosis do not suffer from the same disease.^{418,419,420} The lack of general application of the same definition by physicians who treat IBS amplifies this problem. The fact that three international conferences have been called in Rome to arrive at consensus definitions of IBS implies that the condition is ill defined. To say this is not to disparage the efforts of the experts or the venue of the conferences, but to acknowledge that the absence of a tissue diagnosis impedes understanding of the pathogenesis of IBS. This impediment has caused considerable grief to patients who have IBS. There is an underlying assumption among many lay people and some physicians that IBS is a mental illness and/or a character flaw. Unfortunately, there is no evidence that anyone with IBS can mentally will themselves to “get over it” and stop complaining. This anti-IBS prejudice may be, at least partially, behind the pronounced gender difference seen in referral practices in the incidence and prevalence of IBS;^{421,422} females may predominate, in part, because men are too “macho” and ashamed to admit to being bothered by IBS. Certainly, anxiety can change bowel function; anxiety-associated diarrhea is common and well recognized. That phenomenon, however, is not IBS. On the contrary, IBS is itself depressing and may cause anxiety. No one who experiences the cramping abdominal pain, urgency, bloating, diarrhea, and/or constipation of IBS is likely to be happy about it. As discussed above, signals relayed from the bowel by way of the vagi might also alter mood without coming to consciousness. The public and medical questioning of the legitimacy of IBS as a disease, however, may soon change, because a molecular defect (mucosal SERT expression) has recently been found to be present in the colons of patients with IBS.

Mucosal enterocytes, as described earlier, express SERT in both rodents and humans.^{423,424,425,426,427} Enterocyte SERT is required to terminate the action of 5-HT in the gastrointestinal mucosa, which lacks serotonergic nerves. Loss of SERT is not lethal because the gut expresses backup transporters, such as organic cation transporters 1 and 3 and the dopamine transporter, but motility cannot be controlled stably in the absence of mucosal SERT.⁴²⁸ Mice that lack SERT exhibit diarrhea, constipation, or both in alternation. Patients with IBS also fail to stably regulate colonic motility, and they too may exhibit diarrhea, constipation, or both in alternation. The observation that drugs that affect mucosal serotonergic signaling exert beneficial effects in IBS suggested that mice that lack SERT and patients with IBS might possibly share a defect in SERT expression. Indeed, they do. The expression of SERT is reduced in mucosal biopsies of patients with IBS-C and in those with IBS-D.⁴²⁹ A reduction in mucosal mRNA encoding SERT was documented by means of real-time reverse transcriptase polymerase chain reaction and found by immunocytochemistry to lead to decreased expression of SERT protein in colonic enterocytes. A loss of SERT would be expected to potentiate the action of 5-HT and lead to feedback inhibition of its biosynthesis. Feedback inhibition of 5-HT biosynthesis also occurs in the human colon in IBS. The expression of transcripts encoding Tph1, the isoform of Tph characteristic of EC cells, is decreased in the same colonic mucosal biopsies found to be deficient in SERT. Mucosal SERT expression decreases dramatically in guinea pig colon in which inflammation has been induced by administration of 2,4,6-trinitrobenzene sulfonic acid,⁴³⁰ and in the human colon in ulcerative colitis.⁴³¹ That a reduction in SERT expression should be common to experimental colitis, ulcerative colitis, IBS-C, and IBS-D raises the possibility that inflammation is a common link in all of these entities. A linkage of IBS to inflammation has been suggested in the past, but not definitively established.^{432,433,434,435,436,437,438} Certainly, the symptoms of discomfort, diarrhea, and constipation that are common to ulcerative colitis and IBS may all stem from a shared lesion in mucosal SERT and Tph1. Excessive accumulation of free and active 5-HT, with a resultant potentiation of serotonergic signaling, is the first effect to be anticipated to result from a decline in the function of SERT (Figure 28.3). Potentiation of the action of 5-HT at 5-HT₃ receptors would be expected to lead to

discomfort, while a potentiation of the action of 5-HT at 5-HT_{1P}, 5-HT₄, and 5-HT₃ receptors would all lead to diarrhea. Constipation might be the result of receptor desensitization, and alternation between constipation and diarrhea could result from intermittent receptor desensitization. Indeed, a molecular change in 5-HT₃ receptors has been detected in transgenic mice that lack SERT; the receptors become less sensitive to 5-HT and more likely to desensitize.⁴³⁹ A defect in mucosal SERT expression, whatever its cause, could thus explain the full extent of symptoms in IBS.

In summary, the ENS is an independent nervous system; as a result, the bowel can uniquely exhibit reflexes even in the absence of input from the CNS. The ENS monitors luminal conditions, but has to do so trans-epithelially because no nerves enter the gastrointestinal lumen. Sensory transducer cells in the epithelium respond to mucosal stimuli and secrete transmitters that activate the mucosal processes of both intrinsic (IPANs) and extrinsic primary afferent (sensory) neurons. The best characterized of these cellular transducers is the EC cell, which acts through the secretion of 5-HT. Both the submucosal and myenteric plexuses contain IPANs. Submucosal IPANs initiate peristaltic and secretory reflexes; these cells are stimulated by a receptor activity called 5-HT_{1P}. The release of acetylcholine and CGRP at the terminals of submucosal IPANs and those of other enteric neurons is enhanced by 5-HT₄ receptors. These receptors are presynaptic and, by promoting transmitter release, 5-HT₄ receptors strengthen neurotransmission in prokinetic reflex pathways. 5-HT₃ receptors mediate serotonergic signaling to the CNS; however, they also activate myenteric IPANs and are responsible for fast serotonergic neurotransmission in the ENS. Because of the differential distribution of 5-HT receptor subtypes in the bowel, 5-HT₃ antagonists can be used to treat the nausea associated with cancer chemotherapy without blocking peristaltic and secretory reflexes. 5-HT₃ antagonists are also effective in treating the hypersensitivity of IBS and IBS-associated diarrhea. 5-HT₃ antagonists, however, can be constipating because of their effects on serotonergic neurotransmission within the ENS, and perhaps also because they stimulate myenteric IPANs. The use of 5-HT₃ antagonists in the treatment of IBS is therefore restricted to IBS-D. 5-HT₄ agonists can be used as prokinetic agents to relieve the discomfort as well as the constipation of IBS-C, and also to treat chronic constipation. The safety

of 5-HT₄ agonists is enhanced because they do not initiate peristaltic and secretory reflexes but instead strengthen pathways that are activated by natural means. 5-HT₄ agonists also do not activate nociceptors and thus do not transmit noxious signals to the CNS. Serotonergic signaling in the mucosa and in the ENS is terminated by the action of a plasmalemmal serotonin transporter (SERT), which mediates the transmembrane uptake of 5-HT. Expression of SERT is decreased in the mucosa of patients with IBS-C, IBS-D, and ulcerative colitis. Transcripts encoding tryptophan hydroxylase-1 are also decreased, probably secondary to the potentiation of 5-HT that results from the diminished expression of SERT. SERT expression is also reduced in an experimentally inflamed mucosa. Potentiation of the effects of 5-HT due to the decrease in mucosal SERT expression, which may be followed by desensitization of overly stimulated 5-HT receptors, could account for the common symptoms seen in IBS and ulcerative colitis. Potentiation of 5-HT would be expected to cause discomfort and diarrhea, while desensitization of receptors would lead to constipation. Similar symptoms are seen in patients with IBS and transgenic mice that lack SERT. This commonality of symptoms in patients and animals that share a molecular defect in SERT expression supports the idea that the loss of mucosal SERT contributes to the pathogenesis of IBS.

The “4R” Program *Dan Lukaczer, ND*

Introduction

To review briefly what has been covered so far in this chapter, gastrointestinal (GI) complaints are among the leading reasons patients seek out healthcare practitioners. In the United States, more than 70 million patients suffer some form of GI disorder, which can range from mild discomfort to life-threatening disease. Frequently diagnosed GI-related conditions include gastroesophageal reflux disease, gastritis, peptic ulcer, cholecystitis, diverticulitis, and inflammatory bowel disease. Even more common is the so-called “functional” disorder of irritable bowel syndrome.^{440,441} Many of the most common GI disorders are found with greater frequency in people over 60 years of age and, therefore, are on the rise due to the aging of our population.⁴⁴²

While conditions localized to the GI tract make for an extensive list, GI dysfunction has also been linked to a number of other non-localized systemic conditions. This connection is likely related to a breach in the intestinal barrier, and is often referred to as “leaky gut.” Increased intestinal permeability can lead to many systemic inflammatory and immune-related symptoms. It has been implicated in such unrelated conditions as rheumatoid arthritis, ankylosing spondylitis, eczema, non-alcoholic fatty liver disease, and chronic urticaria.^{443,444,445,446,447,448,449,450} Thus, the normal integrity of the GI tract may be compromised, resulting in distant systemic complaints, even in the absence of overt GI symptomatology.

The ability of the body to maintain healthy GI function, and to heal the GI barrier when its integrity is breached, is integral to protection from many diseases and disorders. However, maintenance of healthy GI function is not a simple task, and understanding how to evaluate and therapeutically support GI function can be a difficult undertaking in a busy practice. For that reason, we will close this chapter with an in-depth discussion of a well-established functional medicine approach to treating GI dysfunction. This method for identifying clinical assessments and interventions that focus on normalizing and optimizing gastrointestinal function has been referred to as the “4R” program, in reference to its four basic clinical steps: remove, replace, reinoculate, and repair. It is designed to provide a focus for evaluation of the status of GI function, with interventions targeted to appropriate nutritional, digestive, probiotic/prebiotic, and antimicrobial therapy. The specific application of the program depends on the nature and course of the patient’s condition, and should be individualized for maximum effectiveness.

The 4R Model

Often in conventional medicine, the clinician asks only how to suppress a particular symptom in a patient. The 4R model asks four primary questions in a patient with GI-related complaints, or complaints whose origins may stem from a breach of GI mucosal integrity:

1. What may need to be *removed* to support healthy GI function? The clinician may need to assess the presence/activity of pathogenic or potentially pathogenic yeast, bacteria, or protozoa in the intestinal

tract, or foods and additives that result in allergic or intolerant responses.

2. What may need to be *replaced* to support healthy GI function? Digestive enzymes, bile salts or stomach acid secretions should be considered.
3. What may be needed to support and/or reestablish a healthy balance of microflora? This step may include *reinoculation* with probiotic and/or prebiotics.
4. What may be needed to support regeneration and *repair* of a healthy mucosal layer? A variety of specific nutrients and phytonutrients are available for this purpose.

Remove

The “remove” aspect of this model focuses on eliminating pathogenic bacteria, viruses, fungi, parasites, and other environmentally-derived toxic substances from the gastrointestinal tract. Foods themselves may be the most important offending agents. Over the course of a lifetime, the gastrointestinal tract processes many tons of food, representing the largest antigenic load confronting the human immune system.⁴⁵¹ (Experts vary on the tonnage, but figures range from 30 to 60 tons of food consumed in the lifetime of the average well-nourished adult.⁴⁵²) During digestion, proteins and large peptides are broken down into amino acids or small peptides within the intestinal lumen, which removes or decreases their antigenic potential. In a healthy intestinal tract, more than 98% of ingested food antigens are blocked from entering circulation by a host of gastrointestinal barrier functions (described earlier in this chapter). In a compromised environment with increased intestinal permeability, significantly more antigens may penetrate to the systemic circulation. These protein fragments, recognized as foreign molecules, stimulate an immune response. In genetically susceptible individuals, autoimmune reactions may therefore result from this increased antigenic load.

Not every adverse response to food qualifies as an immunologically-mediated food allergy. By definition, an immune response only occurs when an antigen/antibody reaction has taken place. Therefore, if a person does not have antibodies against a specific food antigen, he or she cannot have an allergic reaction to that food. However, patients do respond in non-immunological ways. A simple example is a lactase insufficiency, which underlies lactose intolerance, and would not be

considered an allergic reaction. Many food reactions fall into this category.

Some controversy exists with respect to the actual definition of food allergy. Some definitions describe a true food allergy as only an IgE-mediated response, which is also called a type 1 hypersensitivity, whereas a substance that elicits antibodies of any other class is termed antigenic. However, it is becoming clear that not all symptoms of allergic responses can be ascribed to IgE-mediated mechanisms.⁴⁵³ Many allergic responses appear to involve some form of prolonged or delayed reaction to allergens.⁴⁵⁴ IgG antibodies have been implicated as a possible etiological factor in conditions such as atopic dermatitis, asthma, and IBS.^{455,456,457} Therefore, there appears to be some evidence for a role of both IgE and IgG antibodies in the provocation of both immediate and delayed reactions to food allergens.

Food allergies have been suggested as the cause of a variety of symptoms. Clinical studies suggest that 8% of U.S. children younger than six years have evidence of food intolerance, and 2 to 4% of those experience reproducible allergic reactions to foods, most often eggs, milk, peanuts, soy, fish, and wheat.^{458,459} Surveys suggest that 1 to 2% of adult Americans are sensitive to foods, most commonly nuts, peanuts, fish, and shellfish.^{460,461,462} Because delayed food reactions are often difficult to diagnose, these figures likely under-represent the extent of food allergy in the population. Table 28.2 lists some common symptoms and diseases that have been associated with food allergies.

The underlying mechanisms that elicit food-intolerant or allergic responses are complex and controversial, and a variety of assessment techniques for food allergy have been developed. Unfortunately, none are completely adequate, and it appears that the most cost-effective and accurate avenue to determine food allergy is the elimination or oligoantigenic diet, containing only those foods known to pose little risk of an allergic or intolerant reaction. Several studies have shown an association between food allergy and a variety of diseases and symptoms, with avoidance of the suspected foods leading to substantial improvement in clinical symptoms. Therefore, oligoantigenic diets are typically part of a “remove” protocol.^{463,464} If a clinician or patient wants to confirm food sensitivity, the potentially offending food can be reintroduced and symptoms monitored.

Table 28.2 Symptoms and Diseases that may be Associated with Food Allergy

System	Symptoms/Disease
Gastrointestinal	Canker sores, celiac disease, chronic diarrhea, stomach ulcers, duodenal ulcers, recurrent mouth ulcers, indigestion, nausea, vomiting, diarrhea, constipation, gas, gastritis, irritable bowel syndrome, malabsorption, ulcerative colitis, Crohn's disease, colic (babies)
Genitourinary	Bed wetting, chronic bladder infections, nephrotic syndrome, frequent urination
HEENT	Serous otitis media, migraine headaches
Mental/Emotional	Attention deficit disorder, depression, anxiety, memory loss, epileptic seizures, schizophrenia
Musculoskeletal	Joint pain, myalgias, rheumatoid arthritis
Respiratory	Asthma, chronic or allergic sinusitis, constant runny or congested nose, nasal polyps
Cardiovascular	Irregular heart rhythm, vasculitis, inflammation of the veins producing purpura, spontaneous bruising, urticaria, edema
Skin	Eczema, psoriasis, urticaria, red itchy eyes, itchy skin

Equally important in assessment of antigenic stimuli is the myriad array of organisms that reside in or invade the gastrointestinal system. All too often, gut flora assessment is overlooked as a significant source of information concerning systemic or even local health problems. Recognition that intestinal flora could have a major impact on health and disease was first popularized by the Russian scientist Eli Metchnikoff at the turn of the 20th century. Metchnikoff put forth the idea of “dysbiosis,” which he defined as a state of living with intestinal flora that may have harmful or detrimental effects. That idea is now receiving significant scientific validation. The indigenous flora was once thought to be relatively benign. It seems clear that the subject is far more complicated than previously believed.

The number of bacteria in the large bowel alone is greater than 100 billion, which is more than the total number of cells in the human body. These bacteria constitute a powerful chemical factory and can have important effects on human physiology, depending upon their activities. Intestinal bacteria produce toxins and antitoxins, alter chemical composition of foods and drugs, produce and degrade vitamins, produce short-chain fatty acids from fiber, degrade dietary toxins, and inhibit the growth of certain pathogens. Bacterial byproducts can inactivate brush border and pancreatic enzymes, deconjugate bile salts, and hydrolyze bile acids. Problems from a dysbiotic condition often relate to the prolific activity of an altered intestinal microflora. Additionally, through the process of microbial translocation, defined as the passage of both viable and nonviable microbes and microbial products (endotoxins) across an anatomically intact intestinal barrier, gut-derived products may play a role in increasing the systemic immune inflammatory response.⁴⁶⁵ There is evidence that microflora share antigenic determinants with normal tissue and produce cross-reactive antibodies.^{466,467} Bacterial lipopolysaccharides found in the cell walls of gram-negative bacteria have been shown to initiate immune responses and elevate proinflammatory cytokines.⁴⁶⁸ For example, inflammatory diseases of the bowel such as Crohn's and ulcerative colitis, rheumatoid arthritis, and other spondyloarthropathies have been linked to indigenous flora of the gut.^{469,470,471,472,473}

Yeast is another example of indigenous flora that may have detrimental consequences. There is evidence that, in certain individuals, intestinal yeast may result in diverse symptomatology.^{474,475} Although still controversial, the “yeast syndrome” further supports the hypothesis that intestinal organisms can cause or exacerbate systemic or local disease.

The distinction between what is and what is not a pathogen becomes increasingly muddled when one looks at organisms that are clearly not indigenous. Certain parasites, yeasts, and bacteria are traditionally associated with local and systemic consequences. Examples are pathogenic strains of salmonella, giardia, shigella, and campylobacter. However, it does not appear that what has been traditionally described as a pathogen always elicits the same response. Diverse pathogens have been termed weak or strong, and pathogenicity may be determined in part by host immunological competence.⁴⁷⁶ An example is the protozoa *Blastocystis hominis*. Experts disagree sharply on its pathogenicity. In certain studies, it has been associated with colitis, diarrhea, and other gastrointestinal complaints.^{477,478,479,480} Other studies show it to be equally present in asymptomatic and symptomatic individuals, suggesting that it may not always be pathogenic.⁴⁸¹ Weak pathogens may cause disease in some people some of the time. Host resistance and virulence factors are important. Weakly pathogenic strains of salmonella, giardia, and yeast may be other examples of this theme.⁴⁸²

Pathogens can take up colonization anywhere in the GI mucosa, and cell wall components of bacteria, yeasts, and protozoa can be absorbed, which may cause systemic symptoms that are difficult to pinpoint to the pathogen directly. Laboratory tests evaluating microbiology, parasites, and presence of serum antibodies to pathogens are often useful to verify unwanted microbial organisms in the GI tract and monitor response to treatment.

Thus, bacteria, yeasts, and parasites may cause symptoms locally as well as systemically. Food proteins, gut bacterial breakdown products, and environmental toxins can and do reach the systemic circulation. Therefore, removal of offending antigens becomes key to a gastrointestinal restoration program.

Replace

The second clinical step in the 4R program, “replace,” replenishes enzymes and other digestive factors which may be lacking or limited. Enzymes that may at times

need to be replaced include proteases, lipases, cellulases, and saccharidases, which are normally secreted by cells lining the intestine or directly by the pancreas. Other digestive factors that may require replenishment include hydrochloric acid, pepsin, and intrinsic factor, normally secreted by cells in the stomach wall, and bile, synthesized by hepatocytes.

A key ingredient in replacement therapies is hydrochloric acid. Low stomach acidity can result in a variety of symptoms and digestive problems. It is particularly common among individuals older than 60. Reduced hydrochloric acid may impair the absorption of nutrients such as B6, folic acid, calcium, and iron and may also predispose an individual to increased intestinal infections. As hydrochloric acid production depends on zinc, decreased levels may indicate a zinc deficiency as well.⁴⁸³

The small intestine acts as the principal site of digestion and absorption. As mentioned, intact proteins and other large molecules can cross the intestinal lining, even in healthy individuals, to a certain extent.^{484,485} Therapies that involve digestive enzyme supplementation enhance the breakdown of these particles and therefore help to exclude them from crossing that barrier intact. A variety of health conditions, including eczema and steatorrhea, may be ameliorated by enzyme therapy. For example, studies have shown that the digestive enzyme lipase, critical in fat digestion, can be supplemented to relieve problems of fat malabsorption.^{486,487,488} Similarly, many people suffer from undiagnosed lactose intolerance. The digestive enzyme, lactase, has also been used successfully in individuals with the inability to digest lactose.⁴⁸⁹

Food allergies are another area where digestive enzymes may be helpful. Food allergies can be caused by several factors, including the increased supply of intact, poorly digested protein fragments that leak across the gut wall into the systemic circulation. By increasing digestion of dietary protein, protease enzymes decrease the supply of intact proteins available to leak into the bloodstream. Digestive protease enzymes taken orally may also help to digest dietary proteins that are encountered in the bloodstream. Table 28.3 provides some general information on the indications and approaches to the use of HCl and digestive enzymes. Laboratory tests such as gastric analyses, fat absorption tests, and stool analyses may be useful tools to verify the need to replace enzymes and other digestive factors.

Table 28.3 Using Digestive Enzymes and Hydrochloric Acid

Possible Symptoms of Low Stomach Acid	Taking HCl Supplements	Using Digestive Enzymes
- Bloating, belching, burning and flatulence immediately after meals - Dilated blood vessels in the nose or cheeks (Rosacea) - Excess gas in the upper intestine - Indigestion, diarrhea or constipation - Iron deficiency - Multiple food allergies - Nausea after taking supplements - Peeling or cracking fingernails - Rectal itching - Sense of “fullness” after eating - Undigested food in the stool	- Find supplements with at least 600 mg of betaine HCl per tablet or capsule. - Start with one right at the beginning of a meal or immediately after beginning to eat. - At every meal after that, use one more pill. - Continue until 5 tablets/capsules are consumed with each meal, or until warmth occurs in the stomach, whichever occurs first. - The warm feeling indicates too many were consumed, so cut back by one pill at the next meal. - Smaller meals need fewer pills, larger meals more. - Those who need 5 or so capsules should spread them throughout the meal. - After a while, and after repairing the digestive system, patients may produce their own HCl and need fewer capsules. The “warmth” will be present with fewer capsules. Just cut down the dose at that point.	Effective enzymes are available from both animal and plant sources; some are also available by prescription. Use 2–3 just before or at the beginning of a meal. They are generally well tolerated and without side effects. Look for a formula containing at least: - Protease 100,000 USP units - Lipase 20,000 USP units - Amylase 100,000 USP units Vegetarians can take a mixed plant-based form of digestive enzymes. Use 2–3 just before or at the beginning of a meal. Some of these are grown from <i>Aspergillus</i> fungus, so be careful if the patient has mold or yeast sensitivities. Others are derived from pineapple (bromelain) and papaya. Look for a formula with about 500 mg of enzymes per tablet or capsule and containing: - Amylase 100,000 USP units - Protease 100,000 USP units - Lipase 10,000 USP units - Lactase 1600 Lase Digestive bitters may also be tried. Swedish bitters or other aperitifs stimulate digestive function. Herbal bitters including gentian (most common) and artichoke, cardamom, fennel, ginger, and dandelion are also available in more concentrated forms that can be added to water.

Reinoculate

“Reinoculate” is the third step in the 4R gastrointestinal support program. Reinoculate refers to the reintroduction of desirable bacteria, or “probiotics,” into the intestine to reestablish microfloral balance. Bacterial balance in the intestine is critical for proper intestinal permeability. Over 400 different species of microorganisms reside in the human GI tract, and the overall balance of these organisms can profoundly influence gut ecology and health.

Probiotics serve a variety of functions in the gastrointestinal tract. Perhaps the most important function of probiotics is antagonistic activity toward pathogens, which they perform in a variety of complementary ways. First, probiotics assist in colonization resistance—the ability of normal flora to protect against the unwanted establishment of pathogens. Second, probiotics may produce various antimicrobial substances. For instance, *Lactobacillus casei* GG has been shown to produce substances inhibitory toward a broad spectrum of gram-positive and gram-negative pathogens.⁴⁹⁰ Competition for nutrients is a third mechanism. By competing for available nutrient substrate, beneficial bacteria can inhibit the growth of other less favorable flora. Competitive inhibition for bacterial adhesion sites is a fourth mechanism of probiotics. For instance, *Lactobacillus acidophilus* inhibits the adhesion of several enteric pathogens to human intestinal cells.⁴⁹¹ A final mechanism involves systemic host response. For instance, *L. casei* GG, administered orally to subjects with Crohn’s disease, promoted a sIgA response.⁴⁹² These varied actions may decrease the likelihood that pathogens will develop resistance against probiotic agents. Thus, probiotics may be viewed as a vehicle to neutralize or inhibit pathogen activities, or increase or stimulate host immune stimulant activities to the intestinal tract, or both.⁴⁹³

A variety of supplemental sources may be considered helpful in reinoculation. These include cultured and fermented foods containing live bacteria, refrigerated liquid supplements containing live bacteria, or freeze-dried bacteria packaged in powder, tablet, or capsule form. Frequently supplemented species include *Lactobacillus acidophilus*, *Lactobacillus bulgaricus*, *Lactobacillus thermophilus*, *Lactobacillus sporogenes*, *Lactobacillus casei* GG, *Lactobacillus NCFM*, *Saccharomyces boulardii*, *Bifidobacterium bifidus*, *Bifidobacterium longum*, and *Bifidobacterium breve*.

In addition to directly reintroducing bacteria, the reinoculate step may also involve indirectly bolstering the healthy microflora with prebiotics, which selectively promote beneficial synergistic flora without simultaneously supporting pathogenic bacterial growth. When prebiotics are included in the diet, increased levels of fecal fermentation and intraluminal concentrations of short-chain fatty acids (SCFAs), such as propionate, acetate, and butyrate, are produced from fermentation of the fibers by the colonic microflora. SCFAs are thought to supply up to 70% of the energy used by colonic epithelial cells; therefore, prebiotics support improved intestinal integrity and promote intestinal mucosal cell regeneration.⁴⁹⁴ Prebiotics include fructans, inulin and fructooligosaccharides, arabinogalactans, and some soy fibers.^{495,496,497,498} The incorporation of soluble fiber, another important nutrient substrate for probiotics, may also help in the reinoculation process.

Repair

The fourth and final step in a 4R approach is “repair.” Repair refers to providing nutritional support for regeneration and healing of the gastrointestinal mucosa. Part of the support for healing comes from removing insults that continually re-injure or irritate the mucosa, and from promoting healthy microflora. The repair phase of GI restoration benefits from all of the clinical approaches discussed so far.

The GI mucosal cells represent the largest mass (in normal individuals) of rapidly proliferating cells. Repair is necessary whenever there has been a loss of integrity of the GI mucosal structure, function, or both. This loss may be the result of chronic nutritional insufficiency, food allergen and xenobiotic exposure, dysbiosis, pathological intestinal infection, chronic inflammation as in ulcerative colitis, or other less common GI diseases. Assessment of individual need may include a dietary history, nutritional analysis, and any other investigative techniques that reveal the presence of dysfunction, disease, or nutritional insufficiencies.

Once the need for repair has been determined, remediation of any process that resulted in intestinal damage must be done first; second, direct nutritional support of the intestinal cells should be provided through foods or supplements critical to intestinal wall structure and function. Nutrients that play pivotal roles in GI mucosal cell differentiation, growth, functioning, and repair

include glutamine, essential fatty acids, zinc, and pantothenic acid. For instance, dietary deficiency of glutamine is associated with atrophy and degenerative changes in the small intestine following intestinal injury, infection, stress, surgery, and radiation.^{499,500,501} Fish oils, which contain eicosapentaenoic acid and docosahexaenoic acid, have also been shown to ameliorate mucosal injury and attenuate inflammatory conditions of the gut in animal studies.^{502,503,504,505} Research has shown that supplementation with pantothenic acid is important to support the normal healing process.⁵⁰⁶ It has also been found that pantothenic acid is concentrated in gut mucosa and may be important for stimulating the regeneration of the gastrointestinal mucosa in individuals who have chronic ulcerative or granulomatous colitis.⁵⁰⁷ Many individuals with inflammatory bowel disease have zinc deficiencies.^{508,509,510,511}

Summary

The Remove, Replace, Reinoculate, Repair clinical approach is a conceptual program, meant to outline the points to consider when clinically evaluating and applying therapies to a patient with underlying GI dysfunction. While this overall concept describes a basic approach, its use is individualized to the needs of each patient, based on his or her unique clinical condition and nutrient needs. The different steps in this gut restoration program can be applied together, in a unified therapy, or sequentially, beginning with *Remove*. When considered together, the steps of the 4R gastrointestinal support program may address a variety of clinical conditions. Proper assessment of gastrointestinal function and intervention in areas of dysfunction, imbalance, or impairment may have profound effects at the local as well as systemic level.

Chapter 29

Clinical Approaches to Structural Imbalance

- ▶ *Physical Fitness and Exercise*
- ▶ *Manipulative Therapy and Functional Medicine: Clinical Interactions between Structure and Function*

Physical Fitness and Exercise

David Musnick, MD

Introduction

It is important for the functional medicine practitioner to understand the physiological and health benefits of exercise and to be able to prescribe, and help patients achieve compliance with, exercise recommendations. In Chapter 13, the extensive evidence base documenting the many significant health effects of regular exercise was reviewed. In this chapter, we examine the clinical applications of the evidence—how clinicians can build into their practices the prescribing of exercise as a therapeutic and for prevention-oriented intervention. Many health improvement goals are difficult or impossible to achieve without specific “doses” of exercise. This is especially true for people with conditions such as obesity, metabolic syndrome, type 2 diabetes, hypertension, and for cardiovascular prevention. Aerobic exercise is essential for maximum cardiovascular risk reduction, stress management, and mood stabilization. Strength training is essential for injury prevention, slowing of sarcopenia, improvement of lean body mass, and for increasing resting metabolic rate for weight loss. Balance training can decrease injuries and reduce the risk of falling for people with neurodegenerative diseases, as well as for elderly patients and those with osteoporosis.

Overview

The most important elements for integrating exercise prescriptions into clinical care are:

- Include an exercise history as an integral part of the patient’s health history.
- Pay special attention during the physical examination to any cardiac, pulmonary, or orthopedic findings that may restrict the patient’s exercise choices.
- Ask the patient to identify symptoms and key health goals that can be benefited by exercise.
- Educate and motivate the patient about the benefits of exercise.
- Design an exercise program that includes elements of aerobic exercise, strength training, and balance training.
- Ensure that the program you design accommodates the patient’s level of abilities, personal preferences, any orthopedic or medical conditions, and financial resources.

The Exercise History

The following questions can be added to a written patient health history form, or they may be asked in person (in which case, the answers need to be noted in the chart).

Aerobic Exercise

- Do you do any regular cardio/aerobic exercise? If yes, what do you do and how many minutes per day do you do it?
- How many exercise sessions in the average week do you do?
- Do you monitor your pulse rate or perceived level of exertion and, if so, what is your average pulse rate or level of exertion during your exercise?
- Do you have any pain or other uncomfortable symptoms from your aerobic exercise?

Strength Training

- Do you do any strength training/weight lifting?
- What exercises do you do and how many sets, reps, and how much weight do you use?
- What are your goals for your strength training?

Balance Training

- Do you do any lunges or balance exercises?
- Do you tend to fall or feel that you have any difficulties with your balance?
- Do you do any tai chi or other exercise that works on balance?

Personal Issues

- Are you happy with your weight? If not, what do you think is a reasonable weight for you?
- How would you like to look?
- Are you satisfied with your exercise program? If not, why not?
- Are you able to schedule exercise and follow through with your schedule? If not, what is your internal dialog about that?
- What are your controllable and uncontrollable roadblocks to doing your exercise?

Exercise Goals

- What are your goals for exercise? Are you meeting them?
- Do you have any activity goals such as running a race, skiing, etc.? If yes, are you doing any special training for these goals?
- Are you aware of the health benefits that regular exercise can provide in terms of preventing strokes, cancer, and heart attacks?

Health Issues Affecting Exercise

- Do you have any cardiac, lung, neurological, hormonal, or orthopedic problems that might influence your ability to do aerobic or strength-training exercise?

Exercise: Risks and Risk Assessment

Aerobic exercise done at a moderate intensity has some cardiovascular, pulmonary, and musculoskeletal risks, although benefits of exercise strongly outweigh risks.¹ Patients should be adequately screened and given precise exercise prescriptions and education to help them receive the benefits and avoid the risks. Strength training, for example, can lead to strains, back injuries, and tendonitis.

General Health Screening

Before prescribing an exercise program, patients should be screened for a history of angina, myocardial infarction (MI), arrhythmias, hypertension, valvular heart problems (especially aortic stenosis), peripheral vascular disease, and vascular and neurogenic claudication. Screening is also advised for endocrine disorders, including adrenal dysfunction, diabetes, and the metabolic syndrome. It is very important to screen for pulmonary problems, including asthma and COPD. Remember that precipitation of asthma or exercise oxygen desaturation and hypoxia can occur in patients with compromised pulmonary status. Finally, screen for a history of unresolved musculoskeletal injuries, including bursitis, tendonitis, sacroiliac and spine injuries, meniscus and ligament injuries.

Screening for Cardiovascular Risks

Cardiovascular risk factors that should be considered before prescribing exercise include:

- diabetes (fasting glucose and HbA1C)
- high homocysteine levels
- smoking
- positive family history of CAD
- lipid risk factors (high Lip(a), high total and LDL cholesterol, high triglycerides, and trig/HDL ratio >3)
- elevation of cardiospecific C-reactive protein (CRP) and fibrinogen

Order an EKG and consider a stress test in a man over 40 or a woman over 50 if a moderate intensity aerobic program (70–85% of max heart rate) is planned or if the individual has significant risk factors for symptomatic coronary artery disease.

Screening for Pulmonary Risks

Assess for pulmonary risks and functional limitations, including exercise-induced asthma. Consider evaluating the patient with COPD pre and post mild exercise (such as walking). If the O₂ saturation drops below 91, the patient will be a candidate for oxygen during exercise. If the patient is already on oxygen, consider increasing the flow rate during exercise.

Screening for Musculoskeletal Conditions

The following tests can be included in the physical exam if the clinician is trained in and comfortable with basic orthopedic testing. Results will help determine which types of exercise and aerobic equipment are correct for the patient.

- Screen for range of motion, muscle weakness and imbalances, and balance deficits that might increase the risk of injury or degenerative joint disease (DJD) from exercise.
- Do quick scanning exams of the feet, ankles, knees, hips, shoulders, elbows, wrist, and hands.
- Evaluate for adequate range of motion (ROM) and pain with joint motion to assess whether your patient can do the movement patterns of indoor aerobic equipment and classes and outdoor aerobic activities (hiking, skating, running, rowing, etc.).
- Check ankle dorsiflexion (DF)—10 degrees of ankle DF would be preferred for treadmill, stairmaster, and EFX elliptical trainer.
- Check great toe dorsiflexion to see if there is at least 45 degrees for walking, hiking, and treadmill.
- Check for hallux valgus and pes planus to evaluate for orthotic needs during exercise to prevent tendonitis of the foot or knee and excessive stress on the hip and low back. If significant foot flattening (pronation) exists, prescribe orthotics (generic or custom) and more stable shoes.
- Check for knee extension and flexing abilities to evaluate for walking stride and bike seat height.
- Check for tightness in the quads, hamstrings, and IT bands, and prescribe flexibility exercises if tight.
- Check for crepitus in the kneecap joint and pain with squats or lunges. If kneecap pain is present, avoid exercises that require excessive knee flexing (such as bikes or stairmasters), and avoid step aerobics classes.
- Check hip extension. If there is less than 10 degrees, which would be consistent with DJD, limit walking, running, and cross country skiing until extension improves; prescribe cycling and swimming instead.
- Check the strength of the ankle dorsiflexors, knee flexors, and extensors.
- Check gluteal muscle strength in supine and prone positions.
- Do a neurological exam and straight-leg raise to evaluate for lumbosacral sensory or motor radiculopathies.

Characteristics and Benefits of Aerobic Exercise

Aerobic exercise is the repetitive use of muscle in an indoor or outdoor activity that is demanding enough to lead to a demand for increased blood flow to the muscles and a rise in heart rate. Oxygen is used in the electron transport chain and leads to an increase in ATP production compared to anaerobic metabolism. Aerobic metabolism produces 18 times the ATP of anaerobic metabolism. Anaerobic exercise (such as interval high intensity training) generates only 2 ATP, builds up lactic acid, and has higher risks for the heart and musculoskeletal system.

The Benefits of Aerobic Exercise

The health benefits of aerobic exercise have been extensively studied. Researchers have examined different exercise dose-response effects from varying the duration, intensity, and frequency of exercise. Many studies have used a “minimum program,” which is 30 minutes of aerobic exercise in the target heart rate zone, 5–6 days per week. Other studies have reported benefit from two separate 15-minute exercise sessions. The benefits of aerobic exercise do vary depending on the dose of the exercise.^{2,3} It is important to understand these benefits, to educate your patients about them, and to help patients connect their own personal health goals with what can be achieved through proper exercise.

Cardiovascular Benefits of Aerobic Exercise

- Can decrease the risk of all-cause mortality by as much as 30%.^{4,5,6}
- Can decrease the risk of coronary mortality and the risk of fatal myocardial infarction by 40%.
- Can reduce the risk of stroke by up to 25%.⁷
- Can decrease blood pressure.⁸ Systolic and diastolic blood pressures can be reduced by 5–10 mm Hg if the patient is hypertensive. The maximum systolic pressure reduction from exercise alone is estimated to be 10–15 points. If there is weight loss, the drop in BP may be even greater. If a patient is normotensive, exercise can help to maintain a normal blood pressure over time.
- Can increase the ejection fraction and decrease the resting heart rate, both of which may prolong heart function.^{9,10}
- Improves the heart rate reserve.¹¹
- Decreases platelet aggregation.

Cardio CRP. Aerobic exercise can lower an elevated CRP¹² and decrease the risk of elevated normal CRP over time. (Note that if the cardio CRP is elevated, there is a 2–5 times increased risk of MI and other coronary events, and an increased risk for developing type 2 diabetes; in fact, if CRP >2.9, there is an RR increase of 2.7 of developing type 2 DM.) Increased CRP is seen in infections, smoking, type 2 DM, and obesity, all of which are risk factors themselves for developing vascular disease. The most significant drop in CRP is when sedentary adults change to a regular, low-to-moderate intensity exercise program. As exercise intensity, frequency, and duration increase, the CRP continues to drop. Of note is that anaerobic high-intensity training (interval training) can lead to an acute phase reaction and elevate CRP temporarily, so patients should be cautious with interval training.

Cholesterol. Not exercising is as harmful as a high cholesterol. Exercise can decrease the total cholesterol, LDL, and triglycerides.^{13,14} A 1% decrease in total cholesterol is associated with a 2–3% risk reduction of coronary disease. The total cholesterol drop is variable, but appears to be 10–25 points. It is higher when combined with other interventions in obese patients with the metabolic syndrome. Exercise can also help increase the HDL; this is most noticeable in syndrome X patients and others who are overweight and have higher triglycerides. Endurance exercise leads to increased lipoprotein lipase, more breakdown of triglycerides, and more transfer to HDL.

Endocrine Benefits of Aerobic Exercise

- Improves insulin sensitivity¹⁵ and decreases the likelihood of developing NIDDM.
- Decreases the need for medication for hypertension, hyperlipidemia, and dysglycemia if syndrome X or NIDDM is present.
- Decreases the need for insulin use if insulin-dependent diabetic.
- Facilitates weight loss.^{16,17}
- Reduces total body fat.

Other Aerobic Exercise Benefits

- Improves immune function and resistance to infection.¹⁸
- Reduces stress.
- May decrease constipation (improved motility).
- Improves sleep (sleep onset can be disturbed if exercise starts after 8 pm).
- Decrease the risk of developing depression or reduces the severity of depression.^{19,20}
- Improves symptoms of seasonal affective disorder (SAD) from lack of light.
- Facilitates detoxification.
- Reduces the risk of several common cancers: colon, breast, prostate.^{21,22,23}

The Aerobic Exercise Prescription

It is very important to design a specific exercise program for each patient and to write it down. A sample Patient Exercise Calendar is provided in Figure 29.1. For aerobic exercise, the prescription should address the following issues:

Frequency: The number of exercise sessions per day and per week. To achieve basic health goals, patients should do 5–6 aerobic exercise sessions a week. (Patients can do two sessions per day of shorter duration if this is the only way that they can get the exercise in.)

Duration (Length): You would like your patients to do the minimum program of 30 minutes in their target heart rate zone each day. If they are just starting out, they can begin at 15 minutes and add a minute each session until they reach that 30-minute goal. For weight loss, 45–50 minutes a day of aerobic exercise is advised, in either one session or split sessions. Patients can work up to this target gradually. It is reasonable to walk for this long, but most patients should try two different modes of exercise for 20–25 minute sessions each (per day). An example would be 25 minutes on a bike and 20 minutes on a treadmill.

Patient Exercise Calendar

Name _____ Date _____

Circle below all the benefits that you want to experience.

I want to:

- Reduce my risk for fatal heart attacks by as much as 50%.
- Reduce my risk of strokes by as much as 40%.
- Improve my cholesterol.
- Have better blood sugar for diabetes control or prevention.
- Decrease my blood pressure.
- Reduce my risk of injuries.
- Decrease my risk of colon cancer.
- Build muscle.
- Improve my immune system.
- Improve my tone and look better.
- Unload daily stress.
- Decrease my risk of falling.
- Improve my sleep.
- Slow down my aging process.
- Improve my mood.
- Improve my performance in a sport.
- Improve my endurance.
- Improve my flexibility.
- Lose weight.
- Improve strength.

Your maximum heart rate is calculated in this way:

220 - _____ (your age) = _____ (your maximum heart rate).

Your heart rate training zones are a pulse rate per minute of _____ - _____.

Your Exercise Prescription

Aerobic Exercise:

The suggested **length** of your aerobic sessions in your training heart rate zone is _____ minutes.The suggested **frequency** of your exercise sessions is _____ times per week.Your suggested **progress** schedule is: _____Your **exercise options** are: _____

Figure 29.1 Patient exercise calendar

Intensity: The intensity of the aerobic workout should be in the heart rate zone you have recommended, or via a rating of perceived exertion.

Heart rate (pulse) zones are appropriate if a patient is not on a beta blocker or calcium channel blocker that could increase vagal tone and slow the heart rate. These zones are figured as a percentage of the patient's maximum calculated heart rate, which is 220 minus the patient's age. (This may be an underestimate in very fit people.) Multiply the calculated maximum heart rate by 60%, 70%, or 80% to determine the heart rate zone for the patient. Most patients should be in the 70–80% zone, which has been most studied for health benefits. Obese patients or those with a cardiac or pulmonary condition should start in the 60–70% zone and move up when they feel that this zone is too easy (and if there are no symptoms created by the exercising).

For patients with whom heart rate zones are not applicable, a perceived exertion scale can be used. Patients are asked to exercise at an intensity that represents 5–6 on a scale of 10; they should perceive that they are working somewhat hard, but not too hard.

Remind all patients that they should not be excessively winded and should be able to talk during their exercise.

Mode: Select the two or three most appropriate exercise options, taking into account the patient's medical conditions, life patterns and work demands, and health goals. Also consider any findings from the orthopedic exam, as well as what the patient finds enjoyable and can do pain free. It's a good idea for any clinician who is physically able to go to a gym and try out the different aerobic machines with a trainer, acquiring a good feel for the demands these machines make on the body. That will help with individualizing recommendations for your patients. See below for "Exercise Prescriptions for Special Conditions."

Progression: It's important that patients understand how and when to make the initial program more rigorous. For sedentary patients, it is advisable to underdose the duration initially; start at 15 minutes and add a minute for each subsequent exercise session until the desired duration is reached. Sedentary patients can normally begin at 60% of their maximum heart rate, raising it to 70% or the 70–80% zone within a few weeks. Patients who are already exercising, but not to the recommended dose (frequency, duration, or intensity) can start at 70% of the calculated maximum heart rate.

Evaluation: Follow up is essential. Check patient compliance with the aerobic prescription by using a Patient Exercise Record (sample provided in Figure 29.2) and scheduling return visits to discuss results and problems.

Characteristics and Benefits of Strength Training

Strength training can:

- Build more lean body mass (muscle).²⁴
- Improve resting metabolic rate and aid in weight loss.
- Slow sarcopenia (loss of muscle with aging).²⁵
- Build strength²⁶ to decrease the likelihood of injuries and falls.
- Improve function in activities of daily living.
- Stimulate growth hormone release.²⁷
- Improve self confidence.
- Create a positive proactive attitude for other healthy life changes.

Strength Training Prescriptions

In order to write an individualized, specific strength training prescription, the concepts of sets, reps, and resistance must be understood, as well as how body regions work together and what precautions or restrictions to give, depending on the patient's musculoskeletal problems.

The exercise calendar (Figure 29.1) provides space to identify the specific strength training exercises for each patient. Individual recommendations should include those least likely to cause any pain or exacerbation of a current musculoskeletal problem. Instruct patients to do 2–3 sets of 10 repetitions per set; remind them that sets should be pain free. Arm and upper body exercises can be done with free weights or on machines at a gym. Recommend some training before beginning strength training—by reading about the approach, the risks, and how to ensure safe practices, or by enrolling for an in-person training session (or course) with a qualified instructor. For patients with medical or orthopedic problems, an experienced personal trainer who understands how to work with clients of varying abilities and for general health goals is probably an excellent idea.

Patient Exercise Record

Write the dates of each day in the month below. Record in each box the exercise activity you engaged in, the amount of time you spent doing it, and your heart rate (for aerobic exercise). If you did nothing that day, write a note to explain why you did not exercise. Bring this page with you to every clinic visit.

Record any problems associated with exercise:

Date	Type of Exercise	Description of Problem

Figure 29.2 Patient exercise record

Location of Strength Training

A complete strength training program is best done at a gym because of the variety of the equipment available and the multiple options for each type of exercise. If a patient exercises only at home, biceps curls, lunges, and squats will be their primary exercises. With a bench, patients can add a basic row, chest press, and triceps exercise. For the average patient, it is easier to use machines at a gym for most exercises, and to use free weights primarily for biceps curls and lunges.

A Basic Strength Training Program

Prescribe the following exercises to help your patient achieve most of the goals above:

- Biceps curls (with free weights)
- Triceps extensions
- Latissimus pulldowns
- Chest press
- Basic row
- Squats
- Lunges

It is recommended that the healthcare provider learn each of these exercises so as to understand the movement patterns and the muscles used.

Recommending Resistance Levels

Most patients should choose the amount of free weight or the amount on a machine or pulley system that will allow them to do two sets of 10–12 repetitions. In each set, they should experience fatigue in the last 1–2 repetitions. In general, patients should choose a weight that allows performance of the exercise without pain and with normal motion. A fitness trainer can usually choose an appropriate amount of weight for each exercise.

Patients for whom stimulating growth hormone is advisable will need to add squats²⁸ with a bar, use higher resistance, and do three sets of 10 repetitions of each exercise. The last two reps in each set should be very difficult but still safe.

Choosing Strength and Aerobic Exercise Based on Orthopedic Conditions

Wrist sprain or DJD: Strength training—avoid heavy weight lifting (biceps curls), pull-ups, and other forces that lead to wrist distraction. Avoid end-range dorsiflexion in push-ups. Aerobic—avoid boxing and

tae bo classes. Avoid rowing and cross-country skiing, and hold on to the stationary bar while using an elliptical machine.

Elbow pain: Strength training—avoid excessive resistance and repetitive wrist extensions with significant loads. Limit rows, biceps curls, and latissimus (lat) pull downs. Aerobic—avoid rowing and cross-country skiing, caution with kickboxing.

Shoulder AC sprains and rotator cuff tendonitis: Strength training—avoid abduction and flexion above 90 degrees; avoid overhead press, pull-ups and lat pull-downs. Aerobic—avoid cross-country ski machines, rowing machines, tae bo classes and swimming.

Cervical sprain and DJD: Strength training—avoid quick rapid motions such as military press; avoid heavy squats with the neck loaded; avoid lat pull-downs to the posterior neck, overhead press and abdominal crunches with hands on the head, pulling the neck into flexion. Aerobic—avoid running, step aerobics, blading, downhill skiing, snow boarding, tae bo, kick boxing. Caution with bicycling on a road bike. A comfort bike with upright bars and a high stem is better.

Lumbosacral sprain, disc problems: Strength training—avoid lumbar extensions, military press, heavy squats, rapid knee extensions; avoid standing toe touches. Aerobic—avoid diving, snow boarding, downhill skiing, blading, tae bo, and soccer.

Sacroiliac conditions: Avoid exercises that will posteriorly rotate the pelvis in the position of dysfunction. Avoid excessive hamstring stretching. Minimize adductor (groin) exercises. Avoid exercises that involve lumbar flexion and rotation at the same time. Aerobic—avoid running, step aerobics, tae bo and boxing classes.

Hip DJD: Strength training—avoid high resistance and deep squats; avoid walking lunges. Be careful with hip exercises. Aerobic—avoid cross-country ski machines and skiing, Avoid fast swimming, blading, and soccer.

Patellofemoral (kneecap) conditions and IT band syndrome (similar precautions for severe DJD of the knee): Strength training—avoid deep squats, limit depth of lunges. Aerobic—caution with running, step aerobics, steep or fast downhill hiking, bicycling, and stairmaster. With patella tendonitis, all of the above recommendations stand, except bicycling is OK and volleyball, basketball, and all jumping should be avoided.

Ankle sprains: Avoid high-impact aerobic activities initially; avoid basketball, kick boxing, tae bo classes, and other jumping activities.

Balance Exercises for Older Patients and Those with Neurodegenerative Disorders

It is essential to test balance in any patient with a neurodegenerative disorder and in patients over age 60. Preventing falls in your patients is extremely important. Patients who fall can break their hips and wrists or injure their spine. A broken hip is a high risk factor for a deep vein thrombosis. Studies have indicated that physical training can improve balance in the elderly,²⁹ and in people with neurodegenerative diseases like Parkinson's.^{30,31} It is the author's clinical experience of 10 years that balance training can be effective in improving gait, decreasing falls, and decreasing the pain of lower extremity musculoskeletal syndromes.

Testing Balance

There are three planes of balance: the sagittal plane, which is in front and back of the patient; the frontal plane, which is to the left and right; and the transverse plane, which is a rotational plane. Patients can have dysfunction in any or all of these planes. Dysfunction in the sagittal plane and frontal plane are the most common, are the easiest to test, and improve with basic exercises. If the patient shows signs of dysfunction when using a specific balance test, use the test itself as the exercise. Signs of balance dysfunction are wobbling and quick motions of the arms, legs or torso. In general, most static balance exercises can be done in sets of 8–10 and practiced for 5 seconds each, working up to 10 seconds. Patients should work toward equal balance on both legs.

Sagittal Plane Static Balance Tests

Start with these tests if a patient is frail or has questionable balance. The patient stands with both knees bent slightly to engage the quadriceps, and raises one foot slightly off the floor. Measure the time that balance can be maintained on one foot without touching the floor with the raised foot, and without abruptly moving the arms; perform on the other foot, and compare results. At least 5–10 seconds on each foot is desirable. If performing this exercise is too difficult, have the patient stand with hands holding onto a chair back or the exam table. One foot is raised with toes touching the floor, and then the amount of pressure needed for holding onto the chair is gradually lessened. The challenge can be intensified by lifting the raised foot completely off the ground while still holding on. When

balance improves with this approach, the exercise can progress to raising the foot, toe touching the ground, but the hands no longer holding onto the chair. These exercises should be done 5 times on each foot, every other day. Patients should be trained on how to progress to the next level of difficulty, and the instructions should be written down. When patients can do at least 5 seconds on each leg with the foot completely off the floor and without holding on, they can progress to the next set of tests and exercises.

With knees slightly bent and one foot raised completely (or with toe touching the floor), add the following movements: **Level 1**—Arm swinging, both arms together, forwards and backwards in short ranges of motion, up to 45 degrees in front of them. **Level 2**—Arm swinging that reaches an angle of 90 degrees with the floor. **Level 3**—Swing the arms to 90 degrees and increase speed to intensify the challenge in the sagittal plane. Patients should begin with the level that is difficult but possible, and work their way up to the third level. These exercises should be done 5 times on each foot for 5–10 seconds at a time.

Patients with poor sitting balance can do the following exercises while seated on a chair or a physioball. Perform the arm swings as described above, with both feet firmly on the floor (**Level 1**); only the heels touching the ground (**Level 2**); one foot firmly on the floor and the other foot off the floor (**Level 3**).

Sagittal Plane Dynamic Balance Tests

Sagittal plane lunge. The lunge exercise is one of the most functional exercises patients can do for lower body strength and balance. It is useful for virtually anyone who is trying to improve balance and build lower extremity strength. The beginning exercise is 5 lunges on each foot, done at a level in which the patient is slightly unsteady.

For a forward lunge, the patient starts in a standing position with feet parallel to one another and 1–2 shoe widths apart. One foot is moved about 1½ to 2 feet forward of the other, allowing the front knee to bend. The excursion of the lunge is the length from where the toe begins in the start position to where the heel makes first contact with the surface after the lunge. Patients shorter than 5'5" may wish to start with a one-foot excursion and progress the lunge excursion gradually. Most lunges should be performed within a 1½ to 2-foot excursion, although some may exceed this range if

there is an activity that requires longer lunge movements. Before progressing to longer lunges, however, these guidelines should be followed:

1. The movement should be pain-free.
2. Wobbling or swaying of the knees or torso should be minimal.
3. The low back should be in a neutral position, with minimal forward or side-to-side motion of the back with the lunge.
4. Before increasing the excursion of the lunge past 2 feet, try increasing the speed of the lunges while maintaining good control of motion.

Control the speed of knee flexion and stop at about 55–60 degrees. Eventually, patients may go into a deeper lunge. Allow the back knee to bend and the back foot to lift up at the heel. Try to align the forward knee over the first and second toes. Return to the start position by pushing off the front foot. Initially do the lunge with one foot going forward and back.

Same side lunges. Lunge on the right foot for a set of 5–6 repetitions, and then do another set on the left foot.

Alternating lunges. When the form is steady and the patient is not wobbling, the exercise can be done by alternating the feet on each lunge, working up to a set that includes 5–10 lunges on each side.

In most workout routines, patients should do two sets of whichever lunge variation has been chosen.

Tips and precautions. If the forward lunge is painful, try decreasing the depth of knee flexion and add lunges in different directions, especially to the sides. If a lunge is still painful, try unloading it with the arms, as described below. In any lunge, make sure the knee is in line with the foot.

The unloaded lunge, or “no-knee-pain lunge.” Patients may unload a lunge to decrease kneecap pain or if this is the only way they can do a lunge. Ski poles, dowels, or 2 chair backs are used to support part of the body weight through the arms as the knee is bent in the basic lunge. Enough weight should be supported by the arms so that the knees do not hurt and the patient does not wobble.

Static Frontal Plane Balance Tests

Some patients with neurodegenerative disorders and some elderly patients will demonstrate balance dysfunction in the frontal plane, and will benefit from exercises done in this plane.

Frontal plane balance test with arm swing. Have the patient balance on one foot with the knee slightly bent and the opposite foot raised (or toe touching the floor beside the balance foot). Test for balance and time how long the position can be maintained; as balance improves, progress to a level where balancing is a challenge and work there. Exercises should be practiced five times on each foot. **Level 1**—Swing the arms together across the front of the body, side to side in short ranges of motions, at first initially up to 45 degrees. **Level 2**—Do Level 1, but swing the arms faster to increase the momentum and challenge in the frontal plane.

Dynamic Frontal Plane Balance Tests

Frontal plane lunge. This test is performed by having the patient lunge 90 degrees to the right with the right foot, keeping the lunge foot parallel to the non-lunge foot (fixed foot) while bending the ankles, knees, and hips and keeping the back upright. Then the patient pushes off the lunge foot to return to the start position. Patient should do three consecutive lunges to the right and three to the left. Compare their stability, form, and ability to keep the torso steady and the back in good alignment. If there are differences between the sides, or difficulties on both sides, assign this as an exercise with five lunges each to the right and left in a set, and two sets every other day.

Exercise Prescription for Special Conditions

Osteoporosis Prevention Program

Patients with osteopenia or osteoporosis (and perimenopausal females) need exercise as an important element in maintaining bone mass.³² Physical activity provides mechanical stress to bone, which stimulates bone formation. It is important to impact-load both the forearms every other day and the legs on most days. Strength training with the arms can help prevent significant declines in arm bone density, which can lead to a Colles fracture of the radius. Instruct the patient to do a squat with an arm assist by holding onto the backs of two chairs with the feet firmly on the ground. Once they reach a partial squat position, they simultaneously straighten their knees and elbows. Have them do two sets of these along with two sets of 10 biceps curls.

Aerobic exercise that involves moderate-impact loading through the feet and legs can help slow bone loss in the hips and spine. Walking, treadmill, aerobics classes, hiking, elliptical trainer, stairmaster, or jogging are all viable options. Note that the elliptical machine and stairmaster are less impact-loading and should be used with the other more impact-loaded aerobic workouts.

Exercise for CFIDS, Multiple Chemical Sensitivities (MCS), and Fibromyalgia Patients

Patients with fibromyalgia, MCS or CFIDS can benefit from an exercise program,³³ but be very cautious with aerobic exercise, as they may have prolonged fatigue after an aerobic exercise session. Evaluate the level of fatigue they experience with activities of daily living and with aerobic exercise. If significant fatigue is experienced, start with a strength and balance program. Use a functional medicine approach and consider supplements to improve energy.

When the patient reports that enough energy is available to do daily living tasks, consider a low-intensity (50% of max HR) and short-duration (10 minutes) aerobic program two times/week. If the patient tolerates this program, add 1 minute duration every two sessions until the patient has reached 30 minutes per session. Increase the intensity cautiously by 2–5% per week until the patient has reached 60–70% max HR (or the perceived level of effort that is manageable). Decrease the intensity and duration if significant post-exercise fatigue returns.

Supplements may improve a patient's ability to do aerobic exercise. Trying a supplement program for patients with fatigue in daily life activities or for those who can't tolerate brisk walking is a reasonable step. Consider supplementation with CoQ10, 200–300 mg/day and L-carnitine, 1000 mg 3x/day.

Patients with fibromyalgia should be started on a careful strength training program, using only a few upper body exercises at a time (such as biceps curls and triceps exercises). Add one new exercise per week, and use a lower amount of resistance, as these patients are prone to strains and cervical injury. Initiate a walking program, or exercise in a gym, at lowered intensity for 15 minutes, adding one minute every other workout until a duration of 30 minutes, at 60–70% intensity, is reached. Progress to the next intensity level as the patient is able.

Obesity

As noted in the aerobic exercise discussion above, obese patients benefit from longer duration aerobic sessions so they can burn more fat for fuel and more calories. Follow the aerobics guidelines under duration above and progress to 45–50 minute workouts. Incorporate strength training, but let the patient know that this will slow weight loss initially and then will enhance it by helping to increase muscle mass. Most overweight individuals can do stationary bike and the elliptical machines, as well as water aerobics.

The Metabolic Syndrome

Aerobic exercise done as in the paragraph above will increase a patient's sensitivity to insulin and will benefit all aspects of the metabolic syndrome. Patients should experience an improvement in blood pressure and blood sugars within the first two weeks. With only 10–20 pounds lost, significant improvements can be achieved in energy levels, blood sugar, and blood pressure. HDL can be raised and triglycerides lowered. If patients are on numerous insulin-sensitizing supplements and on drug therapy, it is important to monitor their progress closely. After three weeks of regular daily exercise, it is important to monitor the blood pressure and blood sugar to watch out for hypoglycemia. If blood sugars are coming down, medications such as metformin and other drugs may need to be reduced. Blood pressure medication may also be decreased over time, especially if the patient loses weight (10–20 pounds). For overweight patients, ½–1 pound lost per week is a reasonable outcome. If a moderate-intensity exercise program is desired, it is a good idea to obtain a treadmill stress test first to rule out significant ischemia with exercise, as there are many vascular risk factors with diabetes and metabolic syndrome.

Gaining Compliance with an Exercise Calendar

Achieving compliance with the exercise prescription is very important. Emphasize to patients that the exercise calendar and patient record (see Figures 29.1 and 29.2) can be very helpful—particularly when the health benefits have been circled on the top of the page to remind patients daily of their goals. Write in the aerobic exercise prescription with all the details about how you would like them to start and progress.

Circle the strength training exercises at the bottom and write in the balance exercises you are recommending. A normal program would be to recommend aerobic exercise five to six times per week, three strength training sessions per week, and balance exercises every other day. Provide handouts explaining the balance exercises in detail; providing pictures is helpful, as is demonstrating the exercises in the office until the patient can reproduce them accurately.

Other suggestions for improving patient compliance include the following:

- Ask patients to bring their calendar and patient record with them to every clinic visit, so that their program can be evaluated and updated if needed.
- Explain that it's important to record when exercise is not done, and the reason, so that if there are continuing obstacles to performing the complete program, they can be identified and resolved.
- Ask patients to note any symptoms or problems with their exercise, so they can be evaluated and addressed.

When patients bring in their records and calendars, review them, make sure the information is being recorded completely, address any problems, and answer any questions. If you change the prescription, fill out another calendar (and remind patients to circle their goals as well).

If a patient is missing many exercise sessions, gently address the issue by asking questions to elicit the reasons:

1. What do you think is in the way of fitting in all your exercise sessions?
2. Are you having any worrisome symptoms or scheduling problems?
3. If you were to advise me, as if I were your patient, on how to schedule all the recommended exercise, what would be your suggestions?

The most common reasons for poor compliance are:

1. Scheduling difficulties. (Patients may say, "I do not have enough time. I am working too much.")
2. Pain on exercising (usually knee, hip, or back pain).
3. It is too hard.

Whatever the patient's excuse, it is important to address the problem, avoiding criticism or judgment. Any pain problems should be immediately evaluated and addressed—changing the program may be the answer. If the program level is too difficult, move it down a step or two. Help with planning and time management can be

offered, as well as scheduling suggestions (see below). Remind patients of their health goals and the role that exercise plays in achieving them. Validate any exercise that they do. As discussed in Chapter 36, it's rare that a person will immediately adopt new health behaviors and never relapse. Most of us cycle through our process of change several times, and we all need support.

Scheduling Exercise

There are issues to consider in scheduling exercise. Most people will exercise when they have the most energy or when they want to relieve stress; they look for times when there are no other more important demands to be met. It is best to write the schedule down on a daily calendar so that it is not left to memory or chance. In general, patients are more likely to exercise first thing in the morning or at lunch time. If they are going to exercise at lunch time and will be doing moderate intensity exercise, they will likely need at least an hour in their schedule to fit in the 30 minute basic exercise session along with changing and showering. Most people are tired at the end of the day and will not exercise then unless they are very committed to their program. Patients can also schedule and do their exercise in two short periods, such as a 10–15 minute walk at their break times or during their lunch period.

Ask patients when they can schedule exercise sessions and, if they miss the planned time, whether there is a backup time they could use. Note that, for patients with sleep problems, exercise after 8 pm is not a good idea.

Charging and Billing for the Exercise-focused Visit

Visits focusing on exercise should be encouraged. Practitioners can bill for an office visit using the standard time-based procedure codes. If you demonstrate balance or strength exercises, you can add codes such as Kinetic Activities (1–2 units, 15 or 30 minute sessions). You can combine the visit focusing on exercise with reviewing labs or another billable concern or activity.

Summary

Prescribing exercise is a skill that can take a while to develop. Your prescription should be individualized to each patient. It is important to encourage and monitor your patients' compliance to see that goals are being met. For more information on aerobic machines and balance and strength exercise options, there are numer-

ous references including *Conditioning for Outdoor Fitness: Functional Exercise and Nutrition for Every Body*.³⁴ Your patients will notice improved health and wellness outcomes as they achieve their exercise goals.

Manipulative Therapy and Functional Medicine: Clinical Interactions between Structure and Function

David Wickes, DC

Introduction

Changes in structure can affect the function of any component within the body, from the cell to major organ systems. At the simplest level, it is relatively easy to attribute local symptoms and visible asymmetry to structural imbalances. Most practitioners have encountered patients with an antalgic posture secondary to lumbar disc herniation, swelling and ecchymosis from an acute ankle sprain, and the distorted chest wall and unlevelled shoulders seen in severe kyphoscoliosis. Cause-and-effect relationships in these presentations are often easily determined, and a therapeutic management plan can be logically derived. Often unrecognized and unappreciated, however, are the more subtle structural imbalances involving macro- and micro-systems. The rest of this chapter will explore how these structural imbalances may result in local and remote system malfunctions and resulting signs and symptoms.

Structural integrity is essential to optimal function. In biology, as is the case with architecture and engineering, structure influences function. In genomics, amino acid type and sequence determine genetic structure, which in turn affects protein synthesis. Cell and organelle membrane structure affect many local functions, including hormone receptor activity, energy production, permeability, transportation, and storage. In turn, altered cell function affects organ function. Attention is devoted in functional medicine to structural imbalances at all levels in the organism, as well as to the concept that disturbed function can, in turn, lead to changes in structure. Thus, instead of a unidirectional, linear pathway, a more appropriate view is of a complex interactive relationship.

Structural Changes at the Micro Level

The changes that occur in cell membranes incorporating abnormal lipid moieties serve to illustrate the relationship between structure and function at the cellular and tissue level. Cell membranes are composed of a complex double layer of phospholipids, intermixed with cholesterol and glycoproteins. The protein component includes receptors, transport mechanisms, and enzymes. Rather than a static structure, the cell membrane is constantly in a state of flux, reshaping its dynamic structure as function requires.³⁵ During the course of cell and organelle membrane formation or repair, phospholipids and free fatty acids are incorporated into the structure. The free fatty acids are primarily present in the *cis* configuration, although small amounts of *trans* configured fatty acids may also be present normally. Although *trans* fatty acids can be found in dairy products and can also be synthesized by colonic bacteria, most *trans* fatty acids entering the body come from fried or mass-produced foods. If abnormal amounts of *trans* fatty acids are in the bloodstream and interstitial fluids, they may be taken up by the cell and incorporated into the membranes in place of the *cis* fatty acids normally used. Similarly, changes in the relative concentration and availability of normal essential fatty acids may result in alterations of membrane composition. It is now recognized that the changes effected by fatty acids extend beyond the simple concept of membrane lipid replacement to include binding of fatty acids to nuclear receptors and subsequent alteration of gene transcription.³⁶ As these fatty acid abnormalities occur, the cell may develop different membrane characteristics.³⁷ Replacement of membrane lipids with *trans* fatty acids or saturated fats reduces cell membrane fluidity.³⁸ Cell receptors may become inhibited or defective, leading to neurotransmitter or hormonal blockade.³⁹ Prostaglandin synthesis may become disturbed, either due to changes in the type and availability of fatty acids, or to changes in the function of formational enzymes. High levels of *trans* fatty acids may lead to deficiency of essential fatty acids. Membrane permeability and carrier-mediated transport can become disturbed, resulting in intracellular nutrient deficiencies and a reduction in protein formation and secretion. These structural changes at the molecular level have widespread implications in health and disease, including alteration of insulin receptor function and the

potential evolution of the metabolic syndrome and type 2 diabetes, alterations in the immune response to infectious agents and mutagenic stimuli, response to inflammatory disease, and the development of cardiac disease.

Structural Changes at the Macro Level

At the other end of the structural spectrum, the practitioner must consider the possibility that organ functional abnormalities might be the result of, or aggravated by, osseous, connective tissue, and muscle structural lesions. The chiropractic and osteopathic professions were founded after observation and theorization that neuromusculoskeletal abnormalities could lead to organ system dysfunction and frank pathology. In the 1890s, these professions were based upon hypotheses that vertebral malpositioning (“subluxation” or joint “lesion”) could cause spinal nerve or vascular impingement and lead to both local symptoms as well as remote pathophysiology. This evolved over the subsequent decade into a monocausal theory in which the subluxation was felt to be the sole or primary cause of disease. The monocausal philosophy crumbled under scientific scrutiny and was gradually replaced by the current conceptual model, in which the subluxation is considered as one of many possible contributory factors to illness. The subluxation itself has been redefined as an articular dysfunction (joint fixation), with a wide spectrum of theoretical neurobiologic local and remote effects. This current model fits the functional medicine concept in which the clinician must look for the presence of core clinical imbalances, one of which is structural, and any of which may disturb or influence the web-like communication pathways of the body.

Structural imbalances may develop in any part of the neuromusculoskeletal system and may have a primary influence on organ function (i.e., they may cause pathophysiology); or, they may be secondary to either organ system dysfunction or other structural problems. In the functional medicine context, the respective terms somatovisceral and viscerosomatic are too limiting unless conceptually these terms are expanded to include more than just the organ or tissue (see Figure 29.3).

Structural imbalances can be due to congenital or developmental deficits, or they can be acquired. The ability of the organism to adapt to these deficits will determine both short- and long-term effects. Examples of congenital/developmental deficits include anatomical

short legs, joint deformities, hemivertebrae, cervical ribs, absent muscles, and foot deformities. Acquired deficits can result from poor posture, trauma, stress, psychological factors, irritation (e.g., inflammation, toxins), and hormonal alterations (e.g., myalgias and myopathy in hypothyroidism).

Figure 29.3 Somatovisceral interrelationships

The mechanisms by which structural abnormalities at the macro-level result in pathophysiology are diverse (see Table 29.1). Some of these, such as sciatic nerve irritation in vertebral disc disorders, are relatively easy to determine clinically; however, other presentations are subtler. Cervical spine facet injuries and asymmetric facet motion may result in errant proprioceptive signals, initiating dizziness, vertigo, nausea, and possible ocular dysfunction. Aberrant stimulation of afferent and efferent nerves by altered joint motion or local inflammatory mediators may cause both local as well as remote effects. Local changes might consist of pain and muscle spasm. Remote changes include possible referred pain syndromes, facilitation or blockade of spinal cord reflex pathways, and irritation of the reticular activating system. These changes, in turn, may lead to fatigue, disruption of sleep patterns, changes in circulating adrenal hormones, other hormonal fluctuations, and changes in autonomic tone.

Table 29.1 Pathophysiologic Mechanisms in Structural Abnormalities

Aberrant nerve stimulation
Arterial compression (e.g., vascular outlet syndromes)
Autonomic nervous system regulatory abnormalities
Compromised respiration and thoracic cage movement
Focal hypoxia
Mechanical pressure (e.g., herniated intervertebral disc)
Proprioceptive disturbances
Secondary inflammatory changes
Venous and lymphatic congestion

Conditions Associated with Structural Imbalances

Fibromyalgia

Isolated trigger or tender points may be responsible for both local and referred pain patterns. Fibromyalgia is an example of a clinical disorder primarily presenting with somatic complaints, which may become complicated by other organ system dysfunctions if not appropriately managed. When tender points occur in multiple locations, then fibromyalgia or chronic myofascial pain syndrome should be considered. A thorough somatic assessment should include assessment of the 18 classic locations of fibromyalgia tender (trigger) points, with appreciation that the diagnostic criteria for that disorder include finding tender points at 11 or more of these sites.⁴⁰ Fibromyalgia patients may develop dyspepsia, abdominal pain, and other symptoms of the irritable bowel syndrome, and these patients tend to be more sensitive to somatic pain stimuli.⁴¹ Animal studies have demonstrated that noxious somatic afferent stimulation promotes visceral hyperalgesia via spinal cord interactions, establishing a means for the production of intestinal symptoms.^{42,43} It therefore seems reasonable to assess irritable bowel syndrome patients for signs and symptoms of fibromyalgia, and to institute treatment of the somatic component in the hopes of amelioration of visceral symptoms. Fibromyalgia, chronic fatigue syndrome, irritable bowel disease, and other chronic functional disorders often co-exist, so the presence of one of these should prompt a physical assessment for fibromyalgic tender points.

Vascular Changes

Stagnation and congestion of interstitial, lymphatic, and venous fluids is another pathophysiologic state with a somatic component. Although peripheral edema is often dismissed as simply a fluid imbalance, the clinician must keep in mind that these fluids are rich in cellular and humoral components. Accumulation of these fluids in the interstitial compartment may lead to decreased cell nutrition, impaired tissue repair, and compromised immune function. Appropriate exercise, support garments, limb positioning, and lymphatic massage therapy can help reduce edema.

Various outlet disorders can compromise peripheral nerve, arterial, and venous function. Most outlet disorders,

including the common thoracic outlet and carpal tunnel syndromes, have predominantly a neurological presentation because the nerves are more vulnerable to compression than the vascular components. Assessment for these conditions typically involves attempts to reproduce symptoms by functional maneuvers and sustained limb positions. What is often underappreciated is the potential for these outlet syndromes to develop in patients with abnormal spinal function associated with nerve root compression proximal to the additional compression at the outlet (i.e., a “double-crush” injury). Other subtle disorders, including vitamin B12 deficiency, mild hypothyroidism, and inflammatory joint disorders may further predispose the nerve to dysfunction. These conditions, in turn, may also explain why some patients do not respond to manual therapy alone.

Inflexibility and Contractions

A gradual loss of flexibility often goes unnoticed by the patient. Chronic contractions and shortening of ligaments and tendons lead to abnormal compensatory positions and motions, contributing to overall physical stress and a tendency for patients to avoid physical exercise. Sit-and-reach testing assesses for decreased low-back, hip, hamstring, and calf flexibility. Routine evaluation should also include range of motion testing of the neck, trunk, shoulders, and ankles. Abnormalities of peripheral musculoskeletal structures may result in secondary abnormalities of the axial musculoskeletal system.

Vertigo

Another example of the structure-function relationship is benign positional vertigo. This syndrome is characterized by episodic vertigo triggered by certain head positions. The pathophysiologic explanation for this disorder is that calcium carbonate debris suspended in the inner ear fluid becomes lodged or displaced and abnormally stimulates vestibular reflexes. Pharmacologic therapy is generally ineffective; however, a physical maneuver (canalith repositioning procedure, “Epley maneuver”) that places the patient’s head in a particular sequence of positions designed to promote the movement of the debris back into the utricle has shown to be very effective.⁴⁴ Unfortunately, many patients with benign positional vertigo are ineffectively treated because the physician has neglected to

perform the simple functional head positioning tests needed to diagnose the disorder.

The Functional Assessment

Changes in spinal motion can lead to irritation of other spinal structures and possible secondary neurobiological phenomena. Unless accompanied by pain, the patient may be unaware of the restricted motion. Gross screening procedures such as toe touching and assessment of head flexion and extension may fail to detect subtle restrictions. The functional medicine assessment for structural deviations from optimal health should include postural and morphological observations, evaluation for signs of lymphatic or venous congestion, palpation for abnormal muscle tone and fibromyalgia tender points, evaluation of flexibility and joint motion, assessment of respiratory chest motion, and dynamic palpation of the spine (see Table 29.2). Careful postural evaluation can reveal changes in muscle symmetry, scoliosis, and antalgic positioning, but may miss more subtle intersegmental motion abnormalities. Because of this, it is recommended that the functional assessment minimally include direct posterior-to-anterior dynamic palpation using the thumb and index finger or the palm of the hand to test for blocks of restricted intersegmental motion. Respiratory excursion should also be assessed. Unfortunately, the musculoskeletal examination is an oft-neglected component in medical education, and many non-orthopedist clinicians lack competence in the diagnosis and management of musculoskeletal disorders.⁴⁵ Should the functional screening demonstrate abnormalities, or if the practitioner is unfamiliar with the assessment procedures, the patient can be referred to a chiropractic or osteopathic physician for more comprehensive evaluation.

Treatment Approaches

Manipulation in Musculoskeletal Disorders

Back pain. There is substantial evidence that manipulative therapy is effective in the management of many musculoskeletal disorders. Most of this type of therapy is in the form of high-velocity, low-amplitude directional thrusts. Other forms of manipulative therapy, including lower-velocity procedures, localized distraction, general joint mobilization, soft-tissue

manipulation, and instrument-assisted procedures may be useful in specific situations. The most common musculoskeletal complaints seen by chiropractic physicians are low-back pain, neck pain, and cervicogenic headache. Numerous randomized clinical trials have assessed the efficacy of manipulative therapy in acute low-back pain. A meta-analysis in 1992 concluded that spinal manipulation is often of short-term benefit in uncomplicated, acute low-back pain.⁴⁶ A large study in 1995 demonstrated that patients with low-back pain showed rapid improvement with chiropractic manipulation.⁴⁷ A 2004 multicenter randomized clinical trial demonstrated that manipulation improves back function, and that the improvement could be increased by the addition of an exercise program.⁴⁸ Both U.S. and British national clinical practice guidelines for the management of low-back pain recommended the inclusion of manipulation, although the former was not updated in the decade following issuance and is now considered obsolete.^{49,50} A systematic review of 17 clinical guidelines for acute low-back pain found that one of the consistent recommendations was spinal manipulation for pain relief.⁵¹

Flexibility assessment
Spinal and large joint ranges of motion
Spinal passive motion
Paraspinal muscle palpation
Respiratory thoracic cage excursion

Neck pain and headache. The application of manipulation in the management of neck pain has also been studied, although not as extensively. A 2004 review assessed the efficacy of manipulation in neck pain and low-back pain and found that the evidence

was inconclusive regarding its value in acute neck pain, but for acute and chronic low-back pain and chronic neck pain, manipulation was a viable treatment option.⁵² A Cochrane review concluded that manipulation, when done in conjunction with exercise, is beneficial for chronic mechanical neck disorders.⁵³ Cervicogenic headache, i.e., headache caused by cervical spine dysfunction, is commonly treated with manipulation and other physical modalities. These headaches are often associated with autonomic nervous system symptoms, such as nausea and photophobia, and may be confused with migraine headache. A study comparing the effects of high-velocity, low-amplitude manipulation to soft-tissue therapy showed manipulation to be superior, to result in decreased medication reliance, and to decrease the duration and frequency of headaches.⁵⁴

Manipulation and Non-musculoskeletal Disorders

Although the treatment of musculoskeletal disorders with manipulation and other forms of physical medicine is well established, the evidence for the integration of this therapy into the management of non-musculoskeletal conditions is less supported by the literature. Historical perspectives and numerous published anecdotal or small studies suggest that manipulation has a role to play, but rigorous scientific study has lagged well behind the theoretical explanations of mechanism and efficacy.

Structural asymmetry or gait abnormalities may place an additional burden upon the organ systems. In patients with cardiac failure, chronic obstructive lung disease, or other cardiopulmonary disorders, it is easy for the clinician to neglect the musculoskeletal system as a possible contributory factor. Patients with symptomatic knee or hip arthritis have diminished walking speed and a resultant energy cost.⁵⁵ Leg length inequality, either congenital or acquired, may result in compensatory postural adaptations, including pelvic tilt and changes in pelvic and lumbar muscle activity and resultant increased energy demands.

There are complex and overlapping interactions between structure and function at the tissue and organ level. Stimulation of spinal afferent nerves from local spinal and paraspinal tissues or distant organs or somatic structures can result in reflex stimulation of autonomic efferent nerves (i.e., “somatovisceral” reflex) as well as referred pain. These normal reflex pathways can become sustained or exaggerated, leading to dys-

function of the effector organs. The autonomic nervous system has complex interactions with other organ systems, and changes in the activity or tone of the parasympathetic or sympathetic components can trigger a cascade of pathophysiologic events that extend beyond the directly innervated structure. Table 29.3 lists some of the disorders (excluding those classic conditions associated with total autonomic failure) linked to changes in autonomic nervous system balance or regulation.

Table 29.3 Pathophysiology Linked to Autonomic Nervous System Dysfunction

Anxiety
Asthma
Cardiac arrhythmias
Chronic fatigue syndrome
Depression
Fibromyalgia
Gastroesophageal reflux disease
Hypertension
Idiopathic carpal tunnel syndrome
Infertility
Irritable bowel syndrome
Menstrual disorders
Metabolic syndrome
Migraine
Neuropathic pain syndromes
Orthostatic hypotension
Peptic ulcer
Raynaud's phenomenon

As an example of the effects of altered structure upon the autonomic nervous system, movement of inflamed peripheral joints can result in increased blood pressure and heart rate.⁵⁶ Patients with chronic myofascial pain or inflammatory arthritis have heightened sympathetic nervous system activity coupled with diminished cardiac parasympathetic activity.⁵⁷ In fibromyalgia, patients frequently have fatigue, anxiety, headache, weakness, and irritable bowel symptoms. The primary fibromyalgia pain, as well as these accompanying symptoms, may be attributed to a sympathetic hyperdynamic state.⁵⁸ Fibromyalgia patients appear to respond favorably to manipulative care, and such care may further enhance the positive effects of medications.⁵⁹

Some genitourinary disorders have been shown to have a structural basis. The pelvic floor fascia and musculature provide mechanical support to the lower urinary tract and interact with the somatic and autonomic nervous systems to coordinate sphincter and bladder

activity. It has long been appreciated that pelvic floor exercises can be useful in controlling minor stress incontinence. It has now become apparent that interstitial cystitis and the urethral syndrome may also respond to myofascial therapy aimed at the pelvic floor. In a study of 52 patients with some form of interstitial cystitis or the urgency-frequency syndrome, more than 70% had moderate or marked improvement after treatment with manual trigger point therapy to the pelvic floor muscles.⁶⁰ Another study showed that a transvaginal application of a massage technique first described in the 1930s as an intrarectal therapy for coccydynia was effective in relieving symptoms of interstitial cystitis and restoring proper pelvic floor tone.⁶¹

Even in the absence of specific causal relationships between spinal dysfunction and organ dysfunction, the presence of somatovisceral and viscerosomatic reflexes can obscure the clinical presentation. A study of back pain and abdominal pain revealed that the vast majority of patients with abdominal pain experienced concomitant back pain and the vast majority of patients with back pain also had abdominal abnormalities on physical examination.⁶² Whether induced by pain or lifestyle, decreased physical activity and increased caloric intake further complicate these disorders by disturbing diurnal rhythms and shifting the balance between the sympathetic and parasympathetic nervous systems.⁶³

A Common Pathway of Pathophysiology Initiated by Structural Change

Regardless of the initial etiology of the patient's disorder, in many patients there is an associated common pathway of pathophysiology characterized by aberrant activity or noxious stimulation of the nervous system or other feedback mechanisms. This irritation may simply result in localized discomfort or other regional symptoms, or may result in widespread changes in cardiovascular, neurological, humeral, or immune dysfunction. Conversely, primary disorders in those systems may result in secondary dysfunction of the neuromusculoskeletal system. From a functional medicine perspective, clinical improvement may result from introducing a change in one or more of the many interconnected pathophysiologic pathways. The nature and number of these interventions is determined by the patient's anatomical, biochemical, functional, environmental, and psychological individuality. For example, a patient with low-back pain due to a facet disorder may respond well

to manipulation aimed at restoring joint motion, to botanical or pharmacologic agents aimed at neutralizing inflammatory mediators, to massage or biofeedback aimed at relaxing spastic muscles, to acupuncture to restore balance of energy pathways, or to some combination of those modalities. A patient with a non-musculoskeletal disorder resistant to initial therapy should be assessed for possible contributory structural faults, the correction of which might be sufficient to shift the balance towards recovery. Figure 29.4 shows some of the complex interrelationships between structural and functional factors in disease. From this diagram, one can see how different therapeutic approaches may produce the same outcome, and how a management plan that fails to appreciate the web-like connectivity of the body may fail to break a disorder's vicious cycle.

Figure 29.4 Pathophysiology in structural imbalance and autonomic nervous system dysfunction

Summary

Structure is a major determinant of function and this axiom applies to all levels of the body, from the genes to the axial skeleton and body organs. Structural change at the cellular level can result in altered cell metabolism, changes in receptor activity, defective enzyme and protein synthesis, abnormal repair and reproduction, abnormal membrane permeability, and defective signaling. At the other end of the structure spectrum, changes in the neuromusculoskeletal system can result in pathophysiology ranging from pain syndromes to increased energy consumption, somatoautonomic reflex activation, and organ reserve depletion. Because of the complex interactions of the musculoskeletal, humeral, immune, autonomic, and central nervous systems, the clinician should look for imbalances in any of those systems that might contribute to dysfunction in the others. A structural survey should be included in the assessment of any patient with chronic illness.

Bioenergetics, Mitochondrial Function and Oxidative Stress in Functional Medicine
Jeffrey S. Bland, PhD

Introduction

This chapter will develop the concept of oxidative stress from the functional medicine perspective, which represents a mosaic of basic chemistry, biochemistry, cellular physiology, molecular biology, and clinical medicine. There are still gaps in our understanding of this emerging area of basic and clinical science. In order to make clinical connections, the trajectory of the current scientific understanding of oxidative stress will be formulated into a functional model. This model reflects an integration of the principles of energy metabolism and oxidative stress and their relationship to coronary heart disease (CHD), neurodegenerative diseases, autism, diabetes, cancer, arthritis, and syndromes such as fibromyalgia, chronic fatigue syndrome (CFS), and multiple chemical sensitivity.

Knowledge of oxidative stress has significant clinical payoffs. It provides the clinician a lens through which to filter observations that result in new clinical options for both prevention and treatment. The clinical implications of oxidative stress apply to a wide variety of conditions, such as environmental toxicity and the chronic inflammatory disorders of various organs and systems, including the GI system, the liver, heart, brain, joints, and vascular endothelium. Patients with clinical presen-

tations in these areas would be candidates on whom to focus the lens of oxidative stress.

The topic also relates to the controversy surrounding antioxidants. The word “antioxidant” is a non-specific term that can lead to as much confusion as clarity. In this chapter, a more functional understanding of what is meant by antioxidant will be provided, allowing the clinician to better evaluate new information, such as the discussion concerning vitamin E in cancer and heart disease prevention, and what the data really mean.

We will focus mainly on five learning objectives for this chapter:

- This organelle, the mitochondrion, is the so-called energy powerhouse of the cell and has a significant relationship to oxidative stress. We will examine this energy-producing function in some detail.
- We will explore the role of altered bioenergetics in the diathesis of chronic disease. Energy is defined as the ability to do work. What does that really mean in terms of health and disease?
- We want to understand the role of antioxidants in cellular redox control. Redox is a chemical term describing reduction/oxidation reactions, or the transfer of electrons that occurs in oxidative chemistry and cellular physiology.

- We will analyze how various nutrients play a role in establishing proper bioenergetics. Nutrition not only provides the body's fuel (macronutrients), but also facilitates (through micronutrients) proper energy utilization.
- Finally, we will review how all these concepts are related to some common clinical conditions.

Many articles in the literature touch upon these topics. One such article is "New Targets for Heart Failure Therapy: Endothelin, Inflammatory Cytokines and Oxidative Stress."¹ These cardiac disease issues are not cholesterol-related phenomena; they are related to oxidative stress, inflammation, and altered bioenergetics. New observations suggest there may be other factors beyond the traditional risk factors associated with cardiovascular disease (CVD) that contribute to myocardial remodeling. Among the growing list of possibilities are endothelin, inflammatory cytokines, and nitric oxide (NO). NO, along with citrulline, is produced in the vascular endothelium from the amino acid arginine by the enzyme endothelial NO synthase. This process is tightly controlled in order to regulate blood pressure and vascular tone. Other reactive oxygen species (ROS), including superoxide, hydroxyl, peroxynitrite, peroxy radicals, hydroxyl radicals, and singlet oxygen, must also be rigorously controlled. These generally reactive molecules react with cellular components that alter biochemical and/or genetic potential. Most ROS originate internally, due to inefficiencies within the mitochondria, and are part of the price we pay for living in an oxygen-enriched atmosphere. The judicious use of both micro- and macronutrients can minimize their impact on chronic inflammation.

Mitochondria and Energy Production

The mitochondria are our ultimate energy producers. However, they don't release energy in one big burst, but rather as metabolic bumps along the road, analogous to a metabolic Pachinko game. (Pachinko is a Japanese pinball game.) The person playing the game tries to get as much energy out of his or her pinball investment as possible. If the player is good at the game (efficient), the ball can be kept in play for a long time, getting a lot more fun for the money. That's what good metabolism does. It tries to get a lot more activity for the energy by taking many steps along the way in the redox/oxidative pathway. That's why there are so many

metabolic control points in bioenergetic transformation. You don't want to light a fire in your metabolic fireplace and have all the energy lost in one large flame before important metabolic work is completed. People who have lost their metabolic degrees of freedom experience loss of energy efficiency.

The mitochondrion not only generates the bulk of the energy currency of the cell, it is responsible for distributing it. It is the center of bioenergetics. The cells that have the greatest mitochondrial activity are those that do the most aerobic work, such as the cells of the heart and nervous system. Cardiac tissue is an excellent example, in that it is doing the work of muscle contraction 24 hours a day. Seventy-five percent of the heart cell volume, the cardiocyte, is occupied by mitochondria, very tightly packed. In cells that are engaged in a lot of aerobic work and consuming a lot of oxygen (resulting in high energy production), the mitochondria are plentiful and very active. In a sense, the mitochondrion is an organelle that transduces the potential energy in macronutrients into high-energy molecules through the process of oxidation. The mitochondrion takes the chemical potential energy available in food—fatty acids, glucose, and amino acids—and, through the process of redox, converts potential energy into high-energy biomolecules (e.g., ATP, NADH, and FADH₂) that are used by the cell to accomplish its varied tasks. When the mitochondrion is working effectively, it is a clean-burning, oxygen-utilizing, metabolic engine.

The control of this process is closely tied to mitochondrial electron transport through the balance of catabolism (i.e., breaking down large molecules to small ones) and anabolism (i.e., building up large molecules from small ones). Efficient metabolism is controlled by many factors, including hormones, trophic factors, cytokines, neurotransmitters, cofactors, and coenzymes.

The cell membrane is ultimately responsible for the import of nutrients and export of waste products. Macronutrients are broken down to lower molecular weight molecules that can enter the mitochondrion for their terminal oxidation. The mitochondrion is a cellular organelle bounded by a double membrane. The inner membrane is highly folded, creating what are referred to as cristae. Attached to the surface of the cristae are the proteins and enzymes that actually perform the work.

(The cristae of the mitochondrion make one think of a battery wherein energy is stored through an electrical-chemical process of metabolism. No one really knows

how these electrons in oxidative metabolism travel through this system. We think we have the answer through our knowledge of the electron transport chain in the mitochondrion, but we don't really know exactly how it occurs. The electron transport chain involves abstracting energy from food, ultimately generating ATP. This is an amazing process that occurs on the surface of the electron-transporting cytochromes, iron-containing proteins present in the mitochondria. Therefore, the mitochondrion is paramagnetic because there are iron atoms present; it can be polarized in a magnetic or electric field. Studies have been done placing animals in a very high magnetic field strength and noting changes in their mitochondrial bioenergetics.² This raises interesting questions about the influence of electromagnetic energy on mitochondrial bioenergetics.³

As the molecules move across the outer mitochondrial membrane through the inner membrane, they gain access to the enzymes of the Krebs cycle and electron transport chain that are bound to the surface of the inner membrane. As electrons are removed from the di- and tricarboxylic acids of the Krebs cycle, they are captured by proteins of the electron transport chain and transferred in an orderly manner to molecular oxygen. By accepting these electrons, oxygen is reduced to water. Whenever there is oxidation, there must be a concomitant reduction. Electrons are neither lost nor gained; energy and matter are conserved. The electrons exchanged in this process travel down a wire, just as they would from a hydroelectric power generator to an electrical outlet. In this case, the "wire" is the electron transport chain that has various cofactors that assist in the proper regulation of electron flow. Without the integrity of the electron transport chain, the electrons could fly off the wire, as they might in the case of a short circuit on the cord of a lamp. Just as a short circuit can destroy a house, electrons leaking from the electron transport chain can destroy a cell.

It is important to recognize that oxygen, which constitutes 21% of the air we breathe, is a corrosive gas to carbon-based life. Therefore, we have a "love-hate" relationship with oxygen. Using it in the mitochondria as an oxidizing agent (for energy production) provides an energy advantage over the anaerobic organisms that cannot use oxygen. The flip side is that the use of oxygen increases the risk of oxidative injury. This is why complex antioxidant defense systems evolved over millennia to protect against oxidative injury.

On average, about 1% of the oxygen we breathe is converted into high-energy, corrosive oxygen materials, such as superoxide, hydrogen peroxide, and hydroxyl radical. The mitochondria, which are very vulnerable because they are rich in membrane-associated unsaturated fatty acids, have evolved an effective system for protection against oxidation. The protective agents, analogous to the insulation on a wire, are antioxidants present at high levels within the mitochondrion. A high level of antioxidants, consisting of both small molecules and enzymes such as superoxide dismutase and glutathione peroxidase/reductase, can be found in the mitochondria. The small-molecule antioxidants that contribute to the system include lipoic acid, coenzyme Q10, and carnitine (which transports fatty acids across the outer mitochondrial membrane). Together, the components of the system protect the mitochondrion and cell against oxidative stress/injury. In a sense, these agents may be considered "redox buffering agents" that help resist oxidative stress.

If mitochondrial oxidative phosphorylation is blocked or inhibited, then energy production is taken up through metabolic activities occurring in the cytosol. This cytosolic capability results in the reduction of pyruvate to lactate (anaerobic glycolysis). The lactate fermentation is not as energy efficient as oxidative phosphorylation. The process of pyruvate/lactate metabolism is a back-up energy production system. It is a legacy from our anaerobic evolutionary history. When a tissue becomes oxygen deprived, it is shifted to this metabolic state. For example, what happens if you're in a marathon and you run to the 20th mile and "hit the wall"? Biochemically, you have just exceeded your mitochondrial bioenergetic, aerobic, high-efficiency capacity and you are now starting to shift to lactate fermentation, or anaerobic metabolism, as the backup-up system. Lactate is accumulating in your tissues, which lowers cellular pH. As a consequence, you may feel fatigue and pain, as well as changes in mood.

The question therefore arises whether fibromyalgia syndrome could be considered lactic acidosis due, in part, to mitochondrial inhibition occurring at certain trigger points in the muscle body. There are a number of chronic pain syndromes associated with poor muscle performance related to altered mitochondrial bioenergetics. One also wonders about statin drugs and the various kinds of rhabdomyolyses¹ that are associated with muscle pain from these medications. Are these

consequences of the statins altering oxidative chemistry at the mitochondria? One of the important factors for the electron transport pathway is coenzyme Q10 (CoQ10). Statins have been found to decrease CoQ10, which results in interruption of electron transport, thereby blunting mitochondrial oxidative phosphorylation, and possibly inducing a transition to anaerobic metabolism that produces lactic acid. The whole reduction/oxidation balance of the tissue has changed. It's like a 12-volt storage battery that tries to run on eight volts. It doesn't power the system nearly as well at the reduced voltage.

Mitochondrial DNA

For nearly 100 years, it was believed that the source of DNA in cells was restricted to the nucleus and packaged in structures called chromosomes. Isolation of DNA from cells implied the extraction solely of nuclear DNA. We now recognize that while the majority of the DNA in cells is indeed found in the nucleus, a small amount is also found in the mitochondria. The mitochondrial DNA, though small in magnitude relative to genomic DNA, serves an important function. The mitochondrial DNA encodes proteins and RNA molecules that are essential for mitochondrial activity. Mutations in mitochondrial DNA can occur in the absence of mutations that occur in the chromosomes within the nucleus. Despite the fact that several mitochondrial enzymes are encoded on the mitochondrial genome, most are encoded within the nucleus.

The mitochondrion appears to be a very primitive organelle. In fact, molecular paleontologists have dated its origin back 1.6 billion years, so it predates anything we're familiar with in terms of our species. Dr. Lynn Margulis has postulated that long ago a bacterium infected a nucleated cell and so was born the mitochondrion.⁴ If we look at the anatomy of the mitochondria, it would be like taking a facial tissue and packing it into a balloon. That is what the inner mitochondrial membranes are like. On the surface of the inner membrane are bound many enzymes that are like little molecular machines engaged in the process of energy production. All the

bioenergetics reactions are occurring on the surface of those inner mitochondrial membranes. Given the similarity of the mitochondrial DNA to that of bacterial DNA, a number of well-respected medical researchers have discussed the possible origin of the mitochondria in eukaryotic biology.^{5,6} Bacteria lived inside the nucleated cell as symbiotes, providing a competitive edge for the "infected" cell by allowing it to use oxygen more effectively in metabolism.

This provides an explanation for a number of clinical observations—for instance, the example of chloramphenicol-induced hemolytic anemia. Hemolytic anemia is a problem associated with many third-generation antibiotics. If the mitochondrion has the "personality" of a bacteria-like genome, then, when exposed to a hard-hitting antibiotic, it is possible that it can become damaged, resulting in an energy-deficit disorder that leads to conditions such as anemia. Chloramphenicol-induced hemolytic anemia seems to be associated with the sensitivity of the mitochondrion to this antibiotic; it has been found to be sex-linked to the maternal genome. The mitochondrial DNA is inherited predominantly from the mother.^{7,8,9} Sperm have mitochondria (necessary to make energy in order to swim), but they are mostly contained in a section near the tail (the mid-piece, a cytologically distinct region between the head and tail) that falls off after fertilization; thus, rarely do mitochondria from sperm enter the ovum. The ovum, on the other hand, is large and has a tremendous number of mitochondria. Therefore, mitochondrial function and mitochondria-associated diseases are largely a maternally-inherited characteristic.

Mitochondrial DNA is far more susceptible to oxidative injury than nuclear DNA. In the nucleus, the DNA is bound up and tightly coated for protection by histone and non-histone proteins. These protective proteins wrap the DNA in a beautiful helical configuration so that it will not be exposed to agents that might damage it. Through this mechanism, the body has developed protection against nuclear injury to the genome. The genome, when it needs to be read, has mechanisms to selectively unwrap the coat on the DNA so that the reader enzymes can come in. These selective reactions occur by deacetylation and demethylation of the genome that results in reading the specific message on the DNA. In contrast, the mitochondrial DNA is not well protected against injury.¹⁰ It is laid bare, almost like

⁴The destruction or degeneration of skeletal muscle tissue (as from traumatic injury, excessive exertion, or stroke) that is accompanied by the release of muscle cell contents (as myoglobin and potassium) into the bloodstream resulting in hypovolemia, hyperkalemia, and sometimes acute renal failure. (Source: Medline Medical Dictionary.)

the circular chromosome of the bacterium, contrasted to the nucleosome structure of the nuclear DNA.

Mitochondria and Oxidative Stress

Oxidative stress is associated with reactive oxygen species (ROS) that have high reactivity with unsaturated lipids in membranes, proteins, and nucleic acids, thereby changing cellular function. Certain steps in the electron transport chain are facilitated by the reduced form of Q10 and its relationship to the oxidized form of Q10. CoQ10 might then be perceived as an “insulator” on the wire of the electron transport chain. Lipoic acid is also part of this “insulation” through the dihydrolipoic and lipoic acid couple. The enzymes glutathione peroxidase and glutathione reductase help control the concentration of reduced and oxidized forms of glutathione, which is also part of the mitochondrial protection system. Vitamin E also plays a role to shuttle electrons and provide insulation on the wire. If electrons are lost along the electron transport chain, they can do cellular damage. Those electrons are very promiscuous oxidizing agents. Electrons don't want to be alone. They're going to find something to react with. The process by which this occurs is called oxidative stress.

The oxidants released as a result of mitochondrial oxidative stress include superoxide, hydrogen peroxide, singlet oxygen, and hydroxyl radical. These oxidants, in turn, generate lipid peroxides, nitrogen, and sulfur oxide free radical species. Hydroxyl radical is oxidant material produced in cells. In 1975, research I was involved in at the Functional Medicine Research Center (HealthComm International) indicated that hydroxyl radical was produced by cellular systems in humans. (Chemically, hydroxyl radical is the product of the Fenton reaction by which, in the presence of iron, hydrogen peroxide generates a molecule each of hydroxy radical and hydroxide ion.) This hypothesis was criticized by a number of scientists at the time who asserted that there was no way hydroxyl radical could ever be formed in physiological systems because it's only found in high atmosphere particle physics and only occurs in the ionosphere due to high-energy, cosmic radiation exposure. The thought was that we would never get hydroxyl at normal oxygen tension and physiological temperature in the human. Today, however, it is well recognized that hydroxyl radical is generated in human processes and contributes to oxidative stress, along with

other organic molecules in the body, by producing a whole family of other peroxy radicals that also initiate oxidative stress.

This process is more prevalent when a person has a high level of free, available iron, such as seen in hemochromatosis. In such cases, pulmonary and cardiac disease is common because of iron-induced hydroxyl radical pathology. (The only effective treatment is phlebotomy to reduce iron levels.) In tissues that have experienced a hemorrhage, there is a release of free iron from hemoglobin that initiates oxidative stress at the site of the hemorrhage. If you can either decrease the bleeding or increase the antioxidant protection at that site, there will be lowered scarring and tissue injury post-trauma. The antioxidant defense is provided by cellular enzymes such as glutathione peroxidase, glutathione reductase, catalase, and superoxide dismutase.

Normal metabolic processes all produce enough oxidants to rancidify the body each day. Fortunately, our antioxidant enzyme systems defend us from most oxidant damage. The body is working all the time through these enzyme processes and other antioxidants to defend against superoxide, hydrogen peroxide, and hydroxyl radical.

One of the most paradoxical concepts is that the time of greatest oxidative stress is when tissues have the lowest oxygen levels. This sounds counterintuitive, but it's a very important concept clinically. Any time there are low levels of oxygen in a tissue, there are high levels of oxygen radicals. Conditions such as ischemia, hypoxia, anemia, or anything that causes poor delivery of oxygen to tissues (e.g., vascular bed defect, vasoconstriction, trauma to the vessels, infection, edema) create reduced blood flow and oxygen delivery to the tissues. The tissue downstream from the blockade of oxygen is then under high oxidative stress. This is what happens in reperfusion ischemia as a result of coronary artery bypass surgery or a stroke. When a patient is on the pump, it changes the oxygen tension, and when the waiting blood is reoxygenated, it delivers a large shock of oxidants and free radicals.

Every tradition in medicine has had a way of delivering oxygen to tissues to reduce problems of oxidative stress. Today, there is intubation, but before that, there was yoga, deep breathing, respiratory exercises, and physical manipulation, all of which help to deliver oxygen to tissues. If tissues are not being oxygenated, the person is under oxidative stress. Sleep apnea is a good

clinical example of a pro-oxidant situation. Cardiac damage occurs with sleep apnea as a result of oxidative stress-induced phenomena.

Oxidative stress is a cumulative effect of all the factors that increase oxidant production and mitochondrial dysfunction, and decrease antioxidant defense. Let's look at a simplistic example of a vacation in a sunny environment. Before going on vacation, the person has been sedentary. While on vacation, he or she drinks excessive alcohol and exercises very heavily. The person also eats a lot of fried foods and sugar, and is allergic to something during the whole vacation. Finally, the person gets sunburned. All of these factors contribute to oxidative stress; incurring them all at once may overload the body's defense systems. Increased oxidative stress is generally a consequence of a number of factors perpetuating free radical injury to cells.

Mitochondrial Dysfunction and Age-Related Illness

There are several hundred (up to 3,000) mitochondria per cell. The total number of mitochondria in the body obviously greatly exceeds the total number of cells. Over a lifetime, these mitochondria can sustain injury from any number of sources. For example, the mitochondria "remember" many of the toxic exposures that occur over a lifetime, resulting in a decline in their function, including a decline in the synthesis of useful compounds, detoxification capacity, and a loss of control over apoptosis, or cellular suicide. Premature neuronal apoptosis leads to dementia. We want to protect neurons against premature apoptosis unless we really need to get rid of them. If we accelerate apoptosis, we are creating excessive cellular suicide in post-mitotic tissues. The brain is a post-mitotic tissue. Once it's developed, its cells don't get replaced very rapidly. The heart and the muscles are also post-mitotic tissues. We know we can regenerate a liver cell, but it's not so easy for the brain, the heart, or the muscles. That's why these cells are more vulnerable, with age, to cumulative injury. Mitochondrial bioenergetic dysfunctions result in accelerated apoptosis in these tissues.

Think about patients who have been exposed to occupational toxins or xenobiotics, those who are under chronic high stress, those who are heavy smokers or alcoholics and may not be eating properly, those who are taking certain drugs like the nucleoside analog drugs used for HIV treatment, or even those who

have been on repetitive, long-term antibiotics. These are all factors that are injurious to mitochondrial bioenergetics. The lipodystrophy of HIV/AIDS is caused by drugs that injure the mitochondria and alter fat metabolism and the way fat is stored, resulting in diabetes or cardiopathy.

A highly visible example of age-related (i.e., cumulative) oxidative stress was seen on a 2001 cover of *Science News*, showing a photograph of two men of the same age. One is a Navajo chief, looking very old; the other is a Buddhist monk, looking much younger. The principal difference between them was their exposure to the sun. Sun exposure generates free radical oxidative injury to the collagen in subcutaneous tissues, causing them to crosslink and form little puckers in the connective fascia that affect the outer surface of the skin. That's the origin of a sun-induced wrinkle—an example of free radical injury. Another visible example of sun-induced free radical damage is the greater wrinkling on the left versus the right cheek of a truck driver. He is his own "control" because one cheek sustains constant sun exposure over the course of his career, while the other does not. The greater wrinkling on his left cheek is due to radiation-induced free radical injury that is not occurring on his right cheek. These highly visible examples of what cumulative free radical oxidative injury can do to aging tissues help us to understand the similar processes—invisible to the naked eye—that are taking place in our bodies every day.

Mitochondria and Cell Death

There are people who spend their lives trying to figure out the complex processes by which bioenergetics influences all the set points, trigger points, and control points in metabolism. These control points are closely tied to the process of cell suicide, or apoptosis. It seems reasonable that the body would have a built-in way of getting rid of damaged cells to prevent future problems. Over the course of a life, each person will sustain damage to many cells. They can be sloughed off or they can undergo necrosis, but the most common way that damaged cells are removed is through apoptosis. There are cellular signaling pathways that have recently been identified for the control of apoptosis.¹¹ Some of these pathways involve the mitochondria.^{12,13} The mitochondria may receive signals to uncouple their oxidative processes and produce an excess of free radicals, triggering apoptosis.

There are many protective mechanisms that prevent cells from undergoing apoptosis prematurely. Proper regulation of mitochondrial redox is an important part of the protective mechanism against apoptosis. Therefore, the mitochondria have multiple purposes. If cells are damaged or altered, it is important that those cells die before replicating the injury in a daughter cell. However, we don't want our normal, healthy cells receiving a message that unleashes apoptosis and oxidative injury. (We're talking about the release of unpaired electron species that are oxidants, like peroxy or nitroxyl radicals, where there is an oxygen with a single electron on it, and it's hunting for a partner.) In neurology, the word excitotoxicity has to do with processes like the excessive stimulation of the NMDA receptor site in neuronal cells that can activate apoptosis, resulting in premature death. This has been suggested as one possible mechanism resulting in neurodegenerative disorders such as Parkinson's disease.^{14,15,16}

Assessing Oxidative Stress and Oxidative Damage

Free radical oxidative stress can be assessed, not only by analyzing lipid peroxides, but also by measuring levels of isoprostanes in biological samples. These prostaglandin-like molecules are produced in the body by way of oxidative injury to arachidonic acid. Hydroxynonenal can also be measured as an indication of oxidative stress. Another way of assessing is the evaluation of blood levels of another byproduct of oxidation called 8-hydroxy-deoxyguanosine (8OHdG). 8OHdG is produced as a consequence of oxidation of guanosine residues in DNA. It has a close correlation with neuronal oxidative stress, in that about 50% of 8OHdG comes from the central nervous system.

Glutathione status can also be measured as an indication of oxidative stress. Glutathione is an important mitochondrial protector against the production of oxidants. Cellular levels of reduced glutathione are elevated by improving redox and increasing protection of the cell against oxidative injury. The use of N-acetylcysteine supplementation results in a shift of the reduction/oxidation level of the cell more toward a reduced state. This results in a higher glutathione-to-glutathione disulfide ratio in cells. It is important to increase the reduced glutathione levels to increase the total cellular redox capability. During clinical situations demanding increased glutathione reserves, it is important to supplement with N-acetylcysteine, but it is also very impor-

tant to focus on the reduction of triggers to oxidative stress, along with increasing cellular antioxidant status and mitochondrial function. Clinicians should make sure the patient is getting adequate sulfur-rich proteins in the diet (i.e., methionine and cysteine), in that these are the building blocks for glutathione.

Oxidative damage can be analyzed by measuring substances in the plasma, such as serum lipid peroxides, which are an indirect measurement for the amount of oxidative injury that is occurring to unsaturated lipids, particularly the membrane lipids. If you measure serum peroxide levels by the thiobarbituric acid (TBA) test, you're indirectly measuring the "cinders" that result from the oxidative injuries that have occurred to membrane lipids.

Nutrients and Mitochondrial Function

Vitamins and Antioxidants

ATP is the ultimate product of the energy-production process and it is generated by oxidative phosphorylation utilizing electrons that are generated in the oxidation of the organic acids of the Krebs cycle. In order to function properly, the Krebs cycle utilizes a number of coenzymes and cofactors that are derived from vitamins and minerals. Cofactors include thiamine pyrophosphate from thiamin (vitamin B1), riboflavin (vitamin B2) that occurs as flavin-adenine-dinucleotide (FAD), niacin (vitamin B3) that occurs as nicotinamide dinucleotide (NAD), and pyridoxine (vitamin B6) that occurs as pyridoxal phosphate. All of these play a role in serving as facilitators of specific biochemical reactions that occur within the Krebs cycle and, subsequently, in energy production within the mitochondria.

NAD is derived from vitamin B3. It is coupled with its reduced relative, NADH, to store the energy of metabolism. The oxidized form of NAD⁺ is chemically reduced to the higher energy NADH that, in turn, can serve as a reducing agent in specific metabolic reactions. The specific vitamin B3-derived cofactor NAD is, therefore, of critical importance in controlling energy processes in every cell. The symptoms of vitamin B3 deficiency—diarrhea, dermatitis, and dementia—demonstrate its important role in maintaining the energy processes in these target tissues. The same explanation holds true for the other B vitamins, and minerals such as iron and magnesium that regulate enzyme function.

As oxidative stress occurs, the high-energy intermediates (the reduced intermediates) are lower, and the oxidized intermediates are higher, resulting in a decrease in the capacity to produce energy. It's like losing the voltage in the battery of a car. It may still be able to crank, but not on a cold morning. It has lost its energy reserve. People who have lost their energy reserve have higher susceptibility to infection, stress, or trauma. Under conditions of oxidative stress, the ratio of reduced to oxidized intermediates is lower. One of the most important of these ratios is the oxidized-to-reduced-glutathione ratio. When glutathione is oxidized, it yields glutathione disulfide. Under oxidative stress, the ratio of reduced glutathione to glutathione disulfide is reduced from the normal level of 100:1.

It is similar with flavin adenine dinucleotide (FAD), derived from riboflavin. When this coenzyme is reduced by metabolic processes in the mitochondria, it produces the reduced derivative FADHz. The reduced flavin, as does the oxidized flavin, absorbs visible light in the blue, so it has a yellow color. When you consume B vitamins and have color in your urine, what you are really doing is indirectly measuring the riboflavin in the urine as it gets excreted.

Does taking vitamins just produce "expensive urine"? Why would you take nutrient supplements if they are "wasted" by excretion? First of all, if you didn't excrete any vitamins over the course of your life, you would accumulate a lot of vitamins in your body that could build up to a toxic level. They have to be excreted. The question becomes, what happens as they pass through the body? Just because they're eventually excreted doesn't mean they didn't achieve an important health effect on the way through. Vitamins spilled in the urine are neither useless nor detrimental. What we need to know is what happened while they were present in the body. Because they control and influence many bioenergetic reactions, including glycolysis, aminolysis, and lipolysis, vitamins are critically important for functions beyond prevention of deficiency symptoms. Individual vitamin and mineral needs can vary greatly. As Bruce Ames, PhD, has described, there is considerable genetic variation from person to person in how specific nutrients influence their cellular function.¹⁷ Robert Heaney, MD, PhD, recently termed the health problems that result from nutrient intake below the level of individual genetic need as "long-latency dis-

eases."¹⁸ Heart disease, diabetes, osteoporosis, and cancer are all long-latency diseases.

Dietary antioxidants such as vitamin E play an important role. We are all aware that the vitamin E story is still emerging and is more complex than was thought in the 1980s. Clinical trials have suggested that vitamin E supplementation does not have favorable effects in CVD¹⁹ and certain cancers^{20,21} (although studies of other types of cancer have had more positive outcomes²²). Vitamin E appears to play a complex role in modulating oxidative stress through its direct and indirect influence on signaling processes associated with oxidative stress. Indirectly, vitamin E appears to influence inflammatory pathways that, in turn, influence oxidative stress. Vitamin E also has direct effects on cellular mitochondrial redox, altering the signaling pathways so that redox signaling is modified. In some sense, vitamin E might be seen as a cell-signaling messenger. It's not just trapping oxidants. It has a specific cellular effect on regulation of the redox signal to the nucleus. Vitamin E works in combination with many other factors to control redox signaling. In studies that have used vitamin E by itself, the outcome on cellular function is different than when a complex array of antioxidant nutrients is provided, as is found in whole phytonutrient-rich foods.²³ The intervention studies with vitamin E alone may, therefore, not be evaluating the actual contribution of vitamin E, as found in the complex diet, to redox control. This might help explain why results of the Nurses' Study demonstrated a significant reduction in heart disease in women who consumed a diet high in vitamin E,²⁴ but the intervention trials with vitamin E alone have not demonstrated this protective effect.²⁵

What about beta-carotene? In the Finnish smokers' study, the supplemental beta-carotene in the smoking group generated a small but statistically significant increase in lung cancer, a result which disappeared during post-intervention follow-up, confirming the effect.²⁶ The participants in this study were 2- to 3-pack-per-day smokers who were known to consume high levels of alcohol. Smoking and drinking large amounts of alcohol are activities that increase hepatic oxidative stress. It has been demonstrated that oxidative injury to beta-carotene produces harmful oxidation products that can subsequently damage tissue.^{27,28} This suggests that supplementation with high doses of beta-carotene while smoking and consuming excess alcohol loads the dice in favor of potential carcinogenesis.

Charles Lieber, MD, who is at the Bronx VA Hospital and an expert in studying the effects of alcoholism in animals, showed that if you gave beta-carotene supplements to baboons that had been forced to drink alcohol, they had a high incidence of hepatotoxicity.²⁹ A subsequent study in human smokers confirmed this tendency.³⁰ The oxidation products of beta-carotene created the higher risk. Once again, the question that emerges is whether antioxidants, as part of a complex diet, may have a different physiological effect than taking supplemental pharmacological doses of antioxidants.

As was previously mentioned, regulation of redox is tightly tied to control of the glutathione cycle, which is an important part of cellular defense. Glutathione participates in cellular protection in two ways—as an antioxidant through its role in regenerating glutathione from glutathione disulfide, and as a direct conjugate for detoxification. Glutathione conjugation is a fundamental process in the detoxification of drugs and xenobiotics. If a patient has an upregulated detoxification process requiring glutathione, he or she is going to deplete hepatic glutathione, resulting in less available glutathione for the antioxidant function. The result is that the liver is under oxidative stress. The patient develops a functional glutathione insufficiency that alters cellular redox, because the most important single antioxidant in liver cells is the glutathione-to-glutathione disulfide couple.

Fatty Acids

The mitochondrial membrane is a lipid bilayer, made up of phospholipids such as phosphatidylserine, phosphatidylinositol, and phosphatidylethanolamine. These phospholipids are highly unsaturated fatty acid derivatives. Much of the mitochondrial membrane is made up of omega-3 fatty acids. Just as we don't want to cook on the stove with omega-3 fatty acids because they are easily oxidized and become rancid, we also don't want to expose the mitochondrial membrane to excessive free radical oxidants that would cause injury and oxidative damage. Protecting the lipid bilayers of the mitochondrial membrane appears to be one important role of antioxidants.

Fatty acids don't diffuse across the mitochondrial membrane. They're first conjugated to carnitine, which is outside the mitochondria, and then the enzyme carnitine palmitoyl transferase 1 (CPT1) transports the conjugated fatty acid across the mitochondrial membrane. Once within the mitochondrial matrix, the fatty

acid is deconjugated with a second enzyme, CPT2, an isozyme of CPT1. A carnitine deficiency in the cell would affect its ability to burn fats because, without adequate carnitine, fats can't be transported into the mitochondria where they can be metabolized; clinically, this would raise triglyceride levels. There are examples in the literature of the treatment of hypertriglyceridemia by the administration of therapeutic doses of L-carnitine to both humans³¹ and animals.³² (Carnitine is not an essential nutrient. It's called a "conditionally essential nutrient," meaning that a person's need for carnitine at times may exceed his or her own body's ability to manufacture it. There are some nutrients that are essential to everybody, and there are also conditionally essential nutrients that may be, under certain conditions, essential because the body can't make enough of them. CoQ10, lipoic acid, and gammalinolenic acid, or dihomogammalinolenic acid would be examples of conditionally essential nutrients.)

It has also been shown that omega-3 fatty acids, which make up the mitochondrial membrane, are potentially important therapeutic agents to regenerate healthy mitochondrial membranes. Cell membrane fluidity and the role of the membrane in regulation and transport depend on unsaturated fatty acids such as docosahexaenoic acid, or DHA. Brain, mitochondria, and spermatozoa membranes have very high levels of DHA in their composition.^{33,34,35}

The mitochondria have a close relationship with other organelles, like the peroxisomes. The peroxisomes are very important organelles for maintaining energy dynamics. They have the responsibility for breaking down the long-chain fatty acids into smaller, bite-sized pieces that can be transported across the mitochondrial membrane. The mitochondria don't transport long-chain fatty acids. They like shorter fatty-acid chains. The peroxisome is controlled, in part, through regulating factors called orphan nuclear receptors, such as peroxisome proliferator activated receptors (PPARs). The glitazone drugs have been found to work as PPAR gamma (PPAR γ) agonists and the fibrates are PPAR alpha (PPAR α) agonists. Both these families of drugs influence fatty acid metabolism and its relationship to diabetes and heart disease. (There is a new family of drugs that is probably going to be approved soon that are mixed agonists of PPAR α and γ , so that they will better manage the conversation between fats, the mitochondria, and insulin.)

There is a connection between insulin, diabetes, and mitochondrial dysfunction. In diabetes, fatty acid metabolism is altered, resulting in fat infiltration of the liver. Diabetes is not just a sugar problem; it's also a fat problem. When we talk about oxidative chemistry, we are also talking about proper regulation of fatty acid metabolism through control of peroxisome function, and the interface with the nuclear orphan receptor family that signals to the peroxisomes to break down the fats so they can enter the mitochondria for proper energy regulation. That process can be activated by sending a signal to the nuclear orphan receptors to come up to speed and activate fat and sugar metabolism.

Foods

It has been discovered that there are foods in our normal diets that are mixed PPAR α and γ agonists.³⁶ If you eat a phytonutrient-rich diet, you are already getting molecules that speak to your nuclear orphan receptors and cause signaling to occur. More and more foods that contain these PPAR α and γ agonists are being identified. Cinnamon, for instance, contains compounds that influence insulin signaling. Momordica, or bitter melon, has been identified to have PPAR α and γ activity. Licorice³⁷ and ginseng³⁸ also have PPAR α and γ agonist capability. Gymnema also contains phytochemicals that modulate PPAR activity. Conjugated linolenic acid (CLA)³⁹ is a PPAR agonist. Historically, we have been eating foods that have a nutrigenomic influence on these energy control processes. Unfortunately, we've taken a lot of these nutrients out of our food through processing. Certain diseases that have their origin in altered cellular bioenergetics might be caused, at least in part, by the loss of nutrients in our diet that are associated with the control of these important energy-signaling processes.

Clinical Conditions Associated with Altered Mitochondrial Function

What are the clinical conditions that have been associated with altered bioenergetics and mitochondrial dysfunction? The list is long and growing. Oxidative stress, inflammatory cytokines, and changes in endothelial dynamics all appear to be related to heart failure. Strategies designed to modify their pathological effects represent new therapeutic potentials. These often involve improvements in mitochondrial function and redox control. The conditions and diagnoses associated with

mitochondrial defects cut across most sub-specialties in medicine. The list includes skeletal muscle weakness, fatigue, myopathy, including conditions like fibromyalgia syndrome and other myopathic syndromes.

In cardiac disease, it is recognized that Wolff-Parkinson-White syndrome is a mitochondria-associated disorder.⁴⁰ A cardiac mitochondrial defect can lead to a sudden conduction velocity disorder and cardiac failure. Even in fit people, these mitochondrial myopathies can have serious, adverse effects. Leber's optic neuropathy⁴¹ is an inborn error of metabolism relative to mitochondria; certain hepatopathies, specific kidney dysfunctions, and certain endocrine pancreatic dysfunctions, including diabetes, are all associated with mitochondrial problems. Also included in this list are certain colonic obstructive disorders and certain types of sensory deafness and hearing impairment in older-age individuals that occur as a consequence of mitochondrial dysfunction (for which acetyl-L-carnitine has been shown to improve auditory thresholds⁴²). Conditions associated with mitochondrial dysfunction cut across multiple organs, but they cluster in tissues that have the greatest degree of oxygen-processing and bioenergetic activity.

Fatigue-Related Syndromes and Mitochondrial Injury

Greg LeMond is a previous world-class bicyclist and Tour de France winner who retired at the peak of his career with what his physician defined as "acquired mitochondrial myopathy." There is some evidence from the sports world, particularly in endurance events, that elite performance capacity can be lost as a result of overtraining.⁴³ Studies have been published showing mutations in mitochondrial DNA in muscle biopsies from athletes with sustained fatigue.⁴⁴ Their symptoms mimic those of chronic fatigue syndrome, or CFS.⁴⁵

These findings raise the question of whether CFS could be, in part, a clinical syndrome associated with lowered bioenergetic capability due to chronic mitochondrial dysfunction, or mitochondrial injury. Paul Cheney, MD, PhD, a member of IFM in its founding years, was a world-renowned expert and one of the original researchers on CFS.⁴⁶ He did some work with us in the early 1990s showing that his most severe CFS patients had very marked oxidative injury to their mitochondria, resulting in the accumulation of 8-hydroxy-deoxyguanosine (8OHdG), which is a measurement of damaged DNA from oxidative stress. When a certain level of mitochondrial injury was

reached (the point at which around 70% of the mitochondrial genome was damaged, according to Dr. Cheney), he found that it was not possible to bring these patients back to health. They died of many different diagnoses, including cardiopathies.

The mitochondria, in some philosophical sense, has the role of generating the energy necessary to maintain cellular organization, from which the body maintains its structure and function against the natural disordering tendency in the universe, which is called entropy. The reason people eventually die is that the ordering and stabilizing energy systems of the body are exceeded by the natural disordering tendency of the universe. The mitochondrion is constantly supplying the energy to keep order—regeneration, healing, inflammatory response, and rebuilding. If mitochondrial energy production is lost in a certain organ or tissue, that organ or tissue starts shifting its function into a degenerative mode, because it no longer has enough ordering energy.

Maintenance of mitochondrial function in tissues that are high-oxygen consumers is a critical part of a molecular preventive medicine program. The clinician needs to be aware of how to protect the mitochondria against injury, particularly in the post-mitotic tissues (brain, heart, and muscle). These tissues do not regenerate very rapidly. If they are injured, their mitochondria may have a chance to replicate, but if they have mutational injuries, they will replicate the mutation. The problem can then be perpetuated, and a downward cycle can begin.

This situation can be characteristic of patients who present with CFS, fibromyalgia, multiple chemical sensitivities, or anything related to a chronic, mitochondrial, bioenergetic dysfunction. These patients appear worn out; they are dragging around, ragged, and tired. They have lymphadenopathy, fatigue of unknown origin, intolerance to previously well-tolerated exercise, and sleep disturbances. The reasonable assumption that there is an underlying bioenergetic deficit begs the question, why would patients with something like a post-viral fatigue syndrome stay fatigued for years? Why don't they just get over it, like any other kind of limiting infection?

The association with bioenergetics can be understood by taking a look at the general pattern:

- Upregulation and activation of the immune system increase inflammatory mediators and enhance mitochondrial oxidative stress.

- The oxidative injuries are clustered in the gut, liver, muscles, and brain.
- The inflammatory mediators work at the mitochondrial level to alter cell signaling, which causes a reduction of ATP in the mitochondria.
- A reduction in ATP causes the cell membrane binding and transport processes to be modified.
- The membrane pumps are altered and extracellular calcium goes into cells. Cytosolic calcium goes up and, as it does, activation of mitochondrial oxidative stress occurs.

To break the cycle, clinicians and patients must work together to remove the precipitating factors (triggers and mediators) that are activating the immune system. As discussed extensively in other chapters of this book, important steps in such a process may include a detoxification diet, elimination of toxic exposures, removal from the diet of antigens to which the patient is sensitive, and support of intestinal immune function through the 4R program. Then, a metabolic program to regenerate mitochondrial function to the greatest extent possible should be initiated. Depending upon the individual patient's history and condition, a variety of therapeutic agents for mitochondrial resuscitation have been investigated (although significantly more research is needed): CoQ10,^{47,48} lipoic acid,⁴⁹ N-acetylcarnitine,⁵⁰ N-acetylcysteine,⁵¹ vitamin E,^{52,53,54} flavonoids,^{55,56} and omega-3 fatty acids⁵⁷ have all demonstrated beneficial (although often different) effects on mitochondrial function. Finally, basic lifestyle changes to support the treatment program on an ongoing basis should be implemented—as you would expect, these changes include a healthy diet, rich in phytonutrients; moderate exercise suited to the patient's physical condition; decreased stress and improved stress management; and adequate rest. All of these interventions help to break the oxidative stress cycle.

Summary

Clinicians are just starting to learn how important maintaining mitochondrial function is from the functional medicine perspective. Because symptoms indicative of oxidative stress can present with so many different complaints, conditions, and diseases, it is vital to understand the common underlying mechanisms in order to develop clinical strategies that can affect multiple organs and systems through the improvement of

mitochondrial function. Although the evidence base is far from complete, there are strong indications of approaches that can be used effectively. These approaches are highly consistent with therapeutic interventions presented throughout this book for multiple conditions and diseases, providing confirmation of the functional medicine principles upon which they are based.

Oxidative Stress and Autism

Woody R. McGinnis, MD[†]

Introduction

Both indirect and direct markers suggest increased oxidative stress in autism. Indirect markers include lower antioxidant enzymes and glutathione, lower antioxidant nutrients, higher toxin levels, impaired energetics, impaired cholinergic function, greater excitotoxicity, and greater free-radical production.

Direct markers for oxidative injury to biomolecules are abnormal in autism: higher red-cell lipid peroxides; higher urinary isoprostanes, and accelerated lipofuscin deposition in autistic cortex. Brain and gut, pathological in autism, are inherently sensitive to oxidative injury. Double-blind, placebo-controlled trials of potent antioxidants—vitamin C or carnosine—have significantly improved autistic behavior. Benefits of these and other nutritional interventions may be due to reduction of oxidative stress. Understanding the role of oxidative stress should help illuminate the pathophysiology of autism, its environmental and genetic influences, new treatments, and prevention.

Oxidative Stress in Autism

As described earlier in this chapter, when oxidants exceed the antioxidant defense, biological systems suffer oxidative stress, with damage to biomolecules and functional impairment. Autism is a behavioral disorder, with hallmark communication and social deficits. It has been suggested that oxidative stress may play a role in the pathophysiology that underlies the behaviors that define autism.⁵⁸ Another serious behavioral disorder,

schizophrenia, features high oxidative biomarkers⁵⁹ and clinical response to vitamin C.⁶⁰ Many neuroleptic medications used in the treatment of schizophrenia are, in fact, potent antioxidants.⁶¹

Oxidized Biomolecules in Autism

Lipids, proteins, glycoproteins, and nucleic acids are subject to oxidative injury, and a number of analytical methods exist for measurement of oxidative by-products in urine, blood, breath, and organ tissue samples. Oxidized lipids and their protein adducts are commonly used as oxidative biomarkers. Lipids, which comprise biological membranes, are easily oxidized, particularly if highly unsaturated. Direct markers for lipoxidation are higher in autism. In a published study that carefully eliminated dietary and medicinal confounders, levels of red-cell thiobarbituric reactive substance (TBARS, a measure of lipoxidation) in autistic children were twice as high as those in age-matched controls.⁶² Other, preliminary studies found serum lipid peroxides⁶³ and urinary isoprostanes⁶⁴ significantly higher in the autistic group.

Indirect markers are consistent with greater lipoxidation in autism. Low concentrations of highly unsaturated lipids in autistic subjects' red-cell membrane⁶⁵ suggest oxidative depletion. Higher phospholipase A₂⁶⁶ and loss of membrane lipoprotein asymmetry⁶⁷ in autism comport with oxidative effects.

Lipofuscin is a non-degradable matrix of oxidized lipid and cross-linked protein that forms in tissues as a result of oxidative injury. Co-localization of lipofuscin with specific subcellular components or injurious agents may provide clues to neuropathogenesis. In Alzheimer's disease, lipofuscin is associated with oxidized mitochondrial DNA.⁶⁸ Examination of lipofuscin itself can be informative: a documented case of human mercury poisoning with psycho-organic symptoms measured elevated brain mercury, which localized in lipofuscin 17 years after exposure.⁶⁹

Lipofuscin is experimentally induced by strong pro-oxidants such as iron⁷⁰ or kainic acid.⁷¹ In animal experiments, lipofuscin forms initially in the hippocampus, later in the cortical brain.⁷² Also in animals, lipofuscin deposition is retarded by supplementation with vitamins C and E⁷³ or carnitine.⁷⁴ Measurable brain activity is inversely correlated with lipofuscin content.⁷⁵

[†]Adapted, with permission, from McGinnis WR. Oxidative stress in autism. *Altern Ther Health Med*. 2004;10(6):22-36.

Edith Lopez-Hurtado and Jorge Prieto found greater lipofuscin in areas of the autistic cortical brain concerned with language and communication, deficits of which are integral to the diagnosis of autism. After age seven, in comparison to controls, greater lipofuscin was measured in autistics in Brodmann area 22 (Wernicke's, speech recognition), area 39 (reading), and area 44 (Broca's, language production).⁷⁶ (See Figure 30.1.)

Figure 30.1 Areas of greater lipofuscin in autistic brain

In both autistic and control subjects, lipofuscin was always more prominent in Brodmann area 44 at all ages. Analysis by cortical layers showed that the number of cells (both pyramidal and non-pyramidal neurons) containing lipofuscin was larger in layers II and IV. A significant decrease in neuronal cell numbers was found in layers II and IV.⁷⁷ Greater lipofuscin also has been reported in Rett syndrome⁷⁸ (a condition on the autistic spectrum).

The retina, a virtual extension of the brain, is very sensitive to oxidative stress. Greater oxidative stress is associated with flattened electroretinograms and increased retinal lipid peroxides in animal experiments.⁷⁹ In autism, abnormal retinograms with flattened b-waves^{80,81} suggest oxidative retinal injury. Data implying greater oxidation of biomolecules in autism are summarized in Table 30.1.

Table 30.1 Oxidized Biomolecules in Groups of Autistic Children vs. Controls

Elevation/Abnormality	Reference
Red-cell lipid peroxides by TBARS	62
Serum lipid peroxides	63
Urinary isoprostanes	64
Lipofuscin in cortical brain	75
Abnormal retinograms	80, 81

Indirect Markers are Consistent with Greater Oxidative Stress

Indirect markers for greater oxidative stress in autism include lower endogenous antioxidant enzymes and glutathione, lower antioxidant nutrients, higher organic toxins and heavy metals, higher xanthine oxidase and cytokines, and higher production of nitric oxide (NO^{*}), a toxic free radical.

Lower levels of antioxidant enzymes and glutathione in autism (Table 30.2) may stem from lesser production or greater consumption, and impose greater vulnerability to oxidants. Lower antioxidant nutrients (Table 30.3) may be attributed to lower intake or absorption, and/or greater depletion by oxidants. A substantial literature documents increased oxidation of biomolecules and cell injury in relevant nutrient-deficient states.⁸² Nutrient levels affect the status of glutathione and antioxidant enzymes. The glutathione-boosting effect of vitamin C and vitamin E supplementation is well known. Marginal deficiency of vitamin B6 is associated with lower glutathione peroxidase (GPx) and glutathione reductase.⁸³ All forms of GPx contain selenium, and strong correlations exist between low and low-normal blood selenium levels and GPx activity.⁸⁴

Table 30.2 Antioxidant Enzymes and Glutathione in Groups of Autistic Children and Controls

Lower in Autism	Reference
Red-cell GSHPx	337, 338
Plasma GSHPx	93, 343
Red-cell SOD	337
Platelet SOD	338
Red-cell catalase	62
Total plasma glutathione	374
Plasma GSH/GSSG	374

Table 30.3 Antioxidant Nutrients in Groups of Autistic Children vs. Controls

Lower in Autism	Reference
Plasma vitamins C, E and A	211
Red-cell activated B6 (P5P)	160
Red-cell B6 activity by EGOT	211
Red-cell magnesium	211
Red-cell selenium	211
Plasma zinc	244
Red-cell zinc	211

Organic toxins^{85,86} and heavy metals⁸⁷ are strongly pro-oxidant. Impaired detoxification in autism⁸⁸ undoubtedly contributes to higher toxin levels (see Table 30.4). Toxins incite the production of oxidative species by various mechanisms. The volatile organic compounds and insecticides stimulate nitric oxide synthase (NOS).⁸⁹ Copper catalyzes the production of potent hydroxyl radical (OH•), especially when catalase is insufficient.⁹⁰ Mercury is known to increase oxidative stress by blocking mitochondrial energy production and depleting glutathione.

Table 30.4 Higher Pro-oxidants in Groups of Autistic Children vs. Controls

Higher in Autism	Reference
Plasma perchloroethylene, hexane, pentane	211
Red-cell mercury, lead and arsenic	211
Higher provoked urinary mercury	436
Plasma copper	299
Plasma nitric oxide by <i>nitrite</i> + <i>nitrate</i>	94, 95
Red-cell nitric oxide by <i>nitrite</i> + <i>nitrate</i>	96
Circulating cytokines	91
Red-cell xanthine oxidase	62

Circulating cytokines⁹¹ and xanthine oxidase (XO)⁹² are greater in autism, and both generate free radicals. XO actually results from oxidative alteration of xanthine dehydrogenase. Cytokines and XO can be both cause and effect of greater oxidative stress.

Higher Free-Radical Production in Autism

NO•, which is short-lived, is measured indirectly as total *nitrite* + *nitrate*, stable derivatives of NO•. In autism, red-cell⁹³ and plasma^{94,95} total *nitrite* + *nitrate* are elevated, and plasma *nitrite* + *nitrate* levels correlate positively with TBARS.⁹⁶ Excess NO• production is suspected to play a role in other neurobehavioral disorders, including schizophrenia,⁹⁷ Alzheimer’s disease, Down syndrome,⁹⁸ and multiple sclerosis.⁹⁹ It is undetermined whether production of excess NO• in autism localizes to specific organs or tissues. Cytokine-producing cells anywhere can stimulate NO•. Inflammation in the autistic gut and/or brain might contribute significantly to overall NO• production. Excess NO• in the brain would be a serious matter, as it increases apoptosis,¹⁰⁰ leaky blood-brain barrier (BBB),¹⁰¹ and demyelination,¹⁰² any of which might influence neurodevelopment in autism.

Decreased activity of oxidant-sensitive receptors is found in the autistic brain, and this may relate to greater concentrations of NO• specifically, or greater oxidative

stress generally. Cholinergic receptor activity is decreased in the autistic cortex,¹⁰³ and cholinergic receptors are sensitive to NO• toxicity.¹⁰⁴ Gamma-aminobutyric acid (GABA) receptors, generically sensitive to oxidative stress,¹⁰⁵ are reduced in the autistic hippocampus.¹⁰⁶ It is conceivable that a GABA polymorphism associated with autism may lead to an increase in the sensitivity of this receptor to oxidative stress.¹⁰⁷

In the existing literature, lesser cerebellar Purkinje cell numbers and smaller neurons in the entorhinal cortex and medial amygdala are consistent findings in autism,¹⁰⁸ with marked Purkinje cell loss described as the most consistent finding.¹⁰⁹ “Stunted” pyramidal neurons and decreased complexity and extent of dendritic spines are found in the hippocampus.¹¹⁰ These findings are unexplained. Current technology would allow quantification and localization of specific oxidative (and nitrosative) biomarkers and any corresponding microscopic pathology in autistic brain.

Gross and microscopic gut inflammation is very common in autism (see Table 30.5). Corresponding symptoms—pain, constipation or diarrhea, gastroesophageal reflux,¹¹¹ and increased intestinal permeability¹¹²—are also frequent. Inflammation of the distal ileum with adenopathy can be particularly prominent.^{113,114} The inflamed autistic gut probably contributes substantially to greater NO• production in autism, as inflammation of the gut is associated with greater NO• production in other clinical conditions. Plasma *nitrite* + *nitrate* is elevated in childhood colitis.¹¹⁵ In chronic diarrhea, urinary *nitrite* + *nitrate* excretion correlates with leaky gut.¹¹⁶

NO• is potentially antimicrobial.¹¹⁷ Certain viruses and bacteria provoke massive local production of NO• in the gut¹¹⁸ and brain.¹¹⁹ Unfortunately, massive NO• also oxidizes host tissue.^{120,121} Thus, in the gut, excess NO• is known to increase inflammation and permeability.¹²² The young gut is uniquely sensitive to damage by NO•, especially the ileum.^{123,124} Too much NO• can deplete the antioxidant defense, depressing levels of reduced glutathione (GSH).^{125,126} Low GSH, in turn, increases NO•.¹²⁷ Nitrite is known to bind GSH.¹²⁸ In essence, a mutually amplifying positive-feedback loop exists between gut inflammation and NO•.

Table 30.5 Gut Abnormalities in Subgroups of Autistic Children

Abnormality		Autistic Sub-group	Reference
High intestinal permeability	42%	Asymptomatic	112
Reflux esophagitis	69%	Abdominal symptoms	178
Chronic gastritis	42%	Abdominal symptoms	178
Chronic duodenitis	67%	Abdominal symptoms	178
Ileal lymphonodular hyperplasia	89%	Regressed, gut symptoms	113
Colitis	88%	Regressed, gut symptoms	113

A particularly ominous result of excess NO• is increased formation of peroxynitrite (ONOO[−]), which savages biomolecules. ONOO[−] is formed by reaction of NO• with superoxide (O^{−•}); it is much more reactive than its parent radicals. Known targets of ONOO[−] attack with possible relevance to autistic pathophysiology include: tyrosine groups (as in glutamine synthetase and glutathione reductase inhibition), sulfhydryl (-SH) groups, superoxide dismutase (SOD), neurofilaments, ceruloplasmin (releasing pro-oxidant copper), membrane receptors, ion channels, G-proteins, and methionine. ONOO[−] aggressively depletes antioxidants, peroxidizes lipids, and breaks DNA.^{129,130}

NO• is too ephemeral for distant transport. Hypothetically, however, excess NO• originating in one site could cause damage in more distant tissue via higher circulating nitrite and nitrate. Experimentally, intravenous nitrite injures the BBB.¹³¹ Conceivably, higher levels of circulating nitrite from the inflamed autistic gut may be injurious to the brain.

It is thought that excess NO• production outside the gut, by raising levels of circulating stable products of NO• (nitrite, nitrate, and S-nitrosohemoglobin), may lead to greater production of NO• in the gut, with resultant gut inflammation.^{132,133} Nitrite and nitrate are selectively removed from the circulation by the gut.^{134,135} Various bowel flora convert nitrite and nitrate to NO• by enzymatic reduction,^{136,137} which is catalytically favored by low oxygen tension,¹³⁸ as found in the gut. In the case of S-nitrosohemoglobin, NO• release is facilitated by low oxygen tension and the presence of sulfides produced by certain bacteria.¹³⁹

As modulated by gastrointestinal flora, excess production of NO• from any site in the body—including brain or non-localized immune activation—might serve to inflame the autistic gut. Alternatively, a primary inflammatory process in the gut—whether infectious, toxic, or autoimmune—could account for greater total NO• production in autism.

Brain and BBB Sensitivity to Oxidative Stress

The brain is inherently sensitive to oxidative stress due to its higher energy requirements, higher amounts of lipids, iron and auto-oxidizable catecholamines, and lower levels of certain endogenous antioxidant molecules.^{140,141} The protective BBB is relatively sensitive to oxidative damage.¹⁴² Clinical and laboratory findings suggest a leaky BBB in autism. (See Table 30.6.)

Table 30.6 Leaky Blood-Brain Barrier in Autism?

Clues and Predisposing Factors	Reference
High antibodies to brain proteins	150, 151, 152, 153
Sleep disturbance in autism	146, 178
Perivascular lymphocytic cuffing	95
Higher NO/nitrite	94, 95, 96
Lower zinc	211, 244
Higher circulating cytokines	91
Higher heavy metals	211, 436

Clinicians report immediate behavioral improvement in some autistic children at the time of infusion

with GSH.¹⁴³ In healthy animals, transit of GSH across the intact BBB is practically nonexistent, so this clinical response in autistic children may be consistent with leaky BBB in autism.

Also in animals, experimental oxidative injury to the BBB preferentially injures the reticular formation.^{144,145} In autism, widely reported difficulties with falling asleep or staying asleep¹⁴⁶ suggest the possibility of reticular formation dysfunction. Further, the specific nature of rapid eye movement (REM) abnormalities found in autistic sleep disturbance is more typically associated with neurodegenerative disorders in which oxidative stress has been documented.¹⁴⁷ Other than melatonin, which has proved effective in autistic sleep disorders,¹⁴⁸ the effect of antioxidants on autistic sleep disturbance has not been investigated.

Laboratory observations also suggest leaky BBB in autism. Perivascular lymphocytic cuffs reported in three of seven autistic brains¹⁴⁹ are sentinel, though nonspecific. High autoimmune titers to central nervous system proteins in autism^{150,151,152,153} suggest abnormal exposure of the immune system to brain antigens via leaky BBB.

The autoimmune response to brain antigen may be promoted by generation of neoepitopes, which can result from oxidative alteration of host proteins.¹⁵⁴ If they co-exist, autoimmune and oxidative mechanisms in the autistic brain may be mutually reinforcing, as NO• production is increased significantly in autoimmune disease of the central nervous system.¹⁵⁵

Conditions that have been documented in autism are associated with a porous BBB in animals. Higher levels of circulating cytokines,¹⁵⁶ heavy metals,¹⁵⁷ NO•,¹⁵⁸ and nitrite¹⁵⁹ produce leaky BBB in animals. Lower zinc status in autism^{160,161} may be relevant to BBB status. Zinc at physiological concentrations protects the BBB from injury,¹⁶² while zinc deficiency increases BBB permeability, particularly in conjunction with oxidative stress.¹⁶³

Intriguingly, preliminary data suggest overgrowth of gram-negative aerobes in autistic throat and rectal cultures.¹⁶⁴ These organisms produce endotoxin, renowned for permeabilization of the BBB.

Investigation of the autistic BBB is warranted. Enhanced magnetic resonance imaging technology can demonstrate BBB leaks,^{165,166} and scanning electron microscopy can visualize BBB injury, including luminal protrusion, endothelial craters, vacuolation, inclusion bodies, and necrosis, though such visible lesions may be sparse.¹⁶⁷

Greater Oxidative Stress and the Gut

Ischemia/reperfusion studies demonstrate that the gut is very sensitive to oxidative injury.^{168,169} Ingested toxins such as peroxidized fats, electrophilic food contaminants, allergens, and microbial metabolites present a large oxidative burden to the intestinal epithelium.¹⁷⁰ Sufficient quantities of GPx (to reduce peroxides), GST (to reduce electrophiles), and GSH (to facilitate both GPx and GST), are required to protect the gut from oxidation.

As indicated earlier, ileal inflammation and adenopathy are conspicuous in autistic children with gastrointestinal symptoms. Ileum appears more vulnerable to oxidative injury. In animals, GST is 36-fold lower in the distal ileum than in the proximal intestine.¹⁷¹ Double knock-out genes for gastrointestinal GPx result in mucosal inflammation of the ileum, but not other parts of the intestine.¹⁷² In human inflammatory bowel disease, NOS expression is most prominent in the ileum, and the ileum is most sensitive to NO[•]-dependent oxidative injury.¹⁷³

Excess NO[•] is a plausible mediator for common autistic gastrointestinal abnormalities. (See Table 30.7.) NO[•] degrades mucin, which protects the gut from a wide variety of irritants.¹⁷⁴ Excess NO[•] increases intestinal permeability,¹⁷⁵ prevalent in autism.¹⁷⁶ In excess, NO[•] relaxes the esophageal sphincter,¹⁷⁷ and two-thirds of autistic children with gastrointestinal symptoms have reflux esophagitis.¹⁷⁸

Table 30.7 Autistic Gut Abnormalities Possibly Mediated by Excess NO[•]

Abnormality in Autism	Reference
Inflammation	108, 111, 113, 114
Increased intestinal permeability	112
Low esophageal sphincter tone	177
Poor gall-bladder contraction	352
Slow-transit constipation	113

Excess NO[•] inhibits gall bladder contraction,¹⁷⁹ perhaps accounting for lighter-colored stools observed in many autistic children by parents and clinicians. Poor

bile flow impairs nutrition and limits delivery of protective GSH to the gut mucosa.

Excess NO[•] mediates slow-transit constipation.¹⁸⁰ Many autistic children are constipated, some with very large caliber stools. It is possible that malabsorption and floral overgrowths offset clinical constipation in even larger numbers of autistic children.

Oxidative Stress, Low Energy Production, and Excitotoxicity

Oxidative stress, impaired energy production, and excitotoxicity are dynamically related. For instance, energy-producing mitochondria are sensitive to oxidative injury,^{181,182,183,184,185,186,187} and injured mitochondria leak more oxidants into the cellular environment.^{188,189,190} Impaired energy production predisposes to activation of excitatory receptors, decreased intracellular calcium buffering, and increased oxidizing species—as well as apoptosis.^{191,192}

Overstimulation of excitatory receptors results in oxidative neuronal injury,^{193,194} and greater oxidative stress increases release of glutamate and subsequent stimulation of excitatory receptors.^{195,196} Subcellular anatomy correlates with this functional relationship: excitatory glutamate receptors and NOS in the brain and gut¹⁹⁷ are co-localized.

As a general rule, oxidative biochemistry adheres to the following construct, which is both consistent and useful:

Accordingly, greater oxidative stress in autism implies associated problems in energy production and excitotoxicity.

Impaired Energetics in Autism

Magnetic resonance imaging has demonstrated decreased ATP levels in the autistic brain.¹⁹⁸ In blood, higher lactate,^{199,200} higher pyruvate,²⁰¹ higher ammonia, and lower carnitine²⁰² have been documented in groups of autistic children. Collectively, these differences suggest impaired mitochondrial function in autism and, in

Section VI

A Practical Clinical Approach

fact, mitochondrial abnormalities are reported in autistic case studies.^{203,204}

Excess NO• in autism may impair energy production, directly or via ONOO•. Excess NO• reduces oxidative phosphorylation, lowering ATP and increasing lactate.²⁰⁵ NO• directly inhibits complex IV, causing leakage of superoxide and inhibition of GPx.²⁰⁶ ONOO• selectively damages complexes I and III.²⁰⁷ NO• inactivates coenzyme A (CoA), depriving mitochondria of this precious “energy currency.”²⁰⁸ (See Figure 30.2.)

Figure 30.2 Impaired energetics in autism

Excess NO• inhibits CoA by conversion to metabolically inactive S-nitroso-CoA,¹³² with resultant reduction of acetylcholine and ATP¹⁹⁸ production. Lower ATP,¹⁹⁸ higher lactate^{199,200} and higher pyruvate²⁰¹ are found in autism.

Excitotoxic Markers in Autism

Higher extracellular glutamate in the brain is associated with excitotoxicity, especially if energy metabolism is compromised.²⁰⁹ Glutamic acid decarboxylase (GAD) converts glutamate to GABA, and GABA lessens excitotoxicity. A decrement in brain GAD favors excitotoxicity by increasing glutamate and decreasing GABA.

There is ample suggestion that GAD is depressed in autism. The quantity of GAD in the post-mortem autistic brain is decreased by half.²¹⁰ Peripheral measure-

ments are consistent. Red-cell GAD binding affinity is lower,²¹¹ plasma glutamate higher,^{212,213} and plasma glutamine lower²¹⁴ in autism. GAD,²¹⁵ glutamine synthetase,²¹⁶ the glutamate transporter,²¹⁷ and inhibitory GABA receptors²¹⁸ are sensitive to oxidative stress.²¹⁹ (See Figure 30.3.)

Figure 30.3 Excitotoxicity in autism

Higher extra-cellular glutamate and lower GABA increase excitotoxicity. GAD quantity and activity are lower in autism. GAD, glutamine synthetase, and glutamate transporter are sensitive to oxidative stress.

Whether cause or effect of greater oxidative stress in autism, greater excitotoxicity is a reasonable hypothetical and clinical concern. Excitotoxicity can be aggravated by oral ingestion of excitotoxic compounds,²²⁰ and the author joins many other clinicians in advising autistic patients to avoid flavor enhancers such as monosodium glutamate (MSG) and aspartame in food and drink.

Impaired Cholinergics in Autism

Laboratory and clinical observations suggest a significant cholinergic deficit in autism, and this also is consistent with greater oxidative stress. Cholinergic receptor activity is lower in the autistic cerebral cortex.²²¹ Treatment with cholinergic agonists^{222,223} or a precursor (deanol) for acetylcholine²²⁴ is associated with improved behavior in autism.

Response to bethanecol, a specific agonist for the muscarinic subtype of cholinergic receptors, is suggestive. Oral bethanecol (2.5–12.5 mg bid) normalizes dilated pupils, increases bowel motility, and improves sleep pattern and behavior in many autistic children. Occasionally, sudden behavioral improvement is reported immediately after a single dose of bethanecol,²²⁵ and the author confirms this observation.

Neuroimaging reveals cerebral hypoperfusion in autism,^{226,227} worsening with age,²²⁸ and vasodilatation of cerebral microvessels is the province of muscarinic receptors.^{229,230} A possible explanation for the rapid bethanecol response is sudden improvement in cerebral perfusion. Bethanecol may stimulate readily accessible muscarinic receptors in the small blood vessels that perfuse the brain.

Muscarinic impairment in autism may potentiate greater oxidative stress. Experimentally, muscarinic signals are neuroprotective, shielding cells from oxidative stress and apoptosis.²³¹ Muscarinic receptor numbers are decreased by oxidative stress.²³² They are sensitive to NO• toxicity²³³ and, relative to other receptor subtypes, preferentially sensitive to inhibition by ONOO⁻²³⁴ and other oxidants.²³⁵

As discussed earlier, excess NO• in autism may depress CoA, which is important in energy production and a necessary precursor for the cholinergic neurotransmitter, acetylcholine. (See Figure 30.2.) Insufficient CoA renders cholinergic neurons more vulnerable to a variety of toxic insults, including the effects of excess NO•.²³⁶ CoA function has not been studied in autism, but does appear to play an important role in encephalopathies.²³⁷

Antioxidant Nutrients in the Treatment of Autism

A double-blind, placebo-controlled university trial utilized 8 grams per 70 kg body weight per day of oral vitamin C in two or three divided doses in institutionalized autistic children.²³⁸ Some of the cohort had been on doses of up to 4 grams of vitamin C prior to the trial. The cross-over design, comprised of three 10-week periods, included treatment of all subjects with vitamin C for the first 10 weeks. In the second and third phases of the trial, half the children received placebo and then vitamin C. The other half received vitamin C and then placebo.

Psychometric testing was performed after each 10-week phase of the study, but not prior. Total scores on the Ritvo-Freeman (RF) scale, which rates 47 social, affective, sensory, and language behaviors, demonstrated improvement in the group going from placebo to vitamin C, and worsening in the group going from vitamin C to placebo ($p=0.02$). Pacing, flapping, rocking, and whirling behaviors, in particular, corresponded to vitamin C manipulation, and a group of “strong responders” was described as “obvious” to the investigators. No serious side effects were reported in this study,

but clinicians report that excessive stool softening sometimes limits vitamin C dosing in autistic children.

Vitamin C is strongly antioxidant. This suggests—but does not prove—an antioxidant mechanism for its therapeutic effect in these autistic subjects. Antioxidant effects of vitamin C do seem to match known abnormalities in autism. Vitamin C provides good protection against excess NO• and ONOO⁻.²³⁹ Vitamin C is known to protect neurons from glutamate neurotoxicity,²⁴⁰ as glutamate re-uptake involves exchange for vitamin C.²⁴¹ Vitamin C blocks the inhibition of glutamate transport by NO•,²⁴² an effect seen particularly in the presence of copper,²⁴³ higher in autistic blood.²⁴⁴

Carnosine

Carnosine, a naturally-occurring amino acid found in high concentrations in the brain, is a strong antioxidant and neuroprotectant.^{245,246} A double-blind, placebo-controlled 8-week trial of carnosine (400 mg by mouth twice daily) produced significant improvement in autistic children compared with placebo. Psychometric testing demonstrated improvements in vocabulary ($p=0.01$), socialization ($p=0.01$), communication ($p=0.03$), and behavior ($p=0.04$).²⁴⁷ Side effects were inconsequential: sporadic hyperactivity responded to lowering the dose of carnosine, and no child had to discontinue the study due to side effects.

Possible physiological mechanisms for the carnosine effect in autism include its prevention of NO• toxicity,²⁴⁸ binding of free radicals and reactive hydroperoxides, and the ability to complex with metals such as copper.²⁴⁹ The copper:carnosine complex demonstrates antioxidant, SOD-like activity *in vitro*.²⁵⁰

Vitamin B6

Any mechanistic hypothesis for autism should accommodate the successful application of high-dose vitamin B6 pioneered by Bernard Rimland. Multiple controlled trials demonstrate that, in combination with magnesium, B6 improves behavior in many autistic children.^{251,252,253} While serum B6 levels usually are normal, B6 activity, as reflected by erythrocyte glutamic oxaloacetic transaminase (EGOT) assay, is lower in autistic children.²⁵⁴

There is some evidence that pyridoxal kinase, which converts B6 to its active form, pyridoxal-5-phosphate (P5P), is impaired in autism. A preliminary study found

poor binding affinity of pyridoxal kinase in autistic red cells, as reflected by high K_m (Michaelis constant).²⁵⁵ P5P activity in blood is below normal in over 40% of autistic subjects.²⁵⁶ Pyridoxal kinase has many modulators. Lower zinc^{257,258} and energy status in autism may be operant in this context, as pyridoxal kinase requires ATP-facilitated release of zinc from metallothionein for activation.²⁵⁹ The potential role of inhibiting agents should be considered. The strongest pyridoxal kinase inhibitors are the carbonyl agents, which are exogenous compounds such as hydrazine, from jet fuel.²⁶⁰ Endogenous carbonyls result from oxidative alteration of lipids, proteins, and sugars, and are broadly elevated in clinical conditions associated with excess $\text{NO}^\bullet$.²⁶¹ It is not established whether endogenous carbonyls inhibit pyridoxal kinase.

While the cause of poor B6 function in autism is not fully articulated, we can be sure that B6 impairment favors greater oxidative stress. As discussed earlier, even marginal B6 deficiency is associated with lower GPx and glutathione reductase activity, lower reduced-to-oxidized glutathione ratios, and higher lipid peroxide levels.²⁶²

B6 deficiency results in mitochondrial decay and, consequently, oxidative stress.^{263,264} P5P is required for the synthesis of key mitochondrial components: iron-sulfur crystals (for complexes I, II and III), heme (for complex IV),²⁶⁵ and coenzyme Q10.²⁶⁶ Experimentally, P5P protects neurons from oxidative stress, apparently by increasing ATP production and stemming extracellular glutamate.²⁶⁷

Lagging B6 function lowers the excitotoxic threshold. P5P is a necessary cofactor for GAD, impairment of which can increase glutamate receptor activation, $\text{NO}^\bullet$, and oxidative stress.²⁶⁸ P5P protects GAD, sensitive to oxidative impairment,²⁶⁹ from inactivation.²⁷⁰ (Likewise, P5P protects gastrointestinal GPx by complex formation.²⁷¹) Predictably, P5P administration to animals increases brain GAD activity.²⁷²

High doses of B6 may benefit autistic patients by increasing energy production, lessening excitotoxicity, increasing GABA, and reducing oxidative stress. Treatment with B6 also may relieve a state of functional B6 deficiency caused by excess oxidants. The B6 vitamers are highly vulnerable to damage by oxidative species such as hydroxyl ($\text{OH}^\bullet$) and singlet oxygen ($^1\text{O}_2$).^{273,274,275} Oxidative impairment of B6 potentially impairs myriad enzymes and neurotransmitters in autism.

Magnesium

In animal experiments, magnesium deficiency increases $\text{NO}^\bullet$,²⁷⁶ increases lipid peroxides,²⁷⁷ and lowers plasma antioxidants.²⁷⁸ Magnesium supplementation lowers oxidative stress experimentally in animals with higher oxidative stress.²⁷⁹ So, low magnesium favors oxidation.

As a group, autistic children have lower magnesium, as measured sensitively in red cells.²⁸⁰ Double-blind trials demonstrate behavioral improvement and normalization of evoked potential recordings in autistic children receiving combined high-dose B6 and magnesium, but no significant improvement with high-dose B6 or magnesium alone.²⁸¹ The synergism may be a cofactor function. For instance, B6-dependent kinase, which affects diverse muscarinic and GABA-nergic functions, requires both B6 and magnesium.²⁸²

Magnesium also protects against oxidative stress via functions unrelated to B6. Production of NADPH requires magnesium for reduction of glutathione. ATP synthase, which catalyzes energy production by oxidative phosphorylation, is magnesium sensitive.²⁸³ In the brain, magnesium normally blocks overactivity of excitatory receptors by modulating calcium channels.²⁸⁴

Zinc

Lower zinc status in autism has been well documented. Red-cell zinc, a sensitive indicator of zinc sufficiency, is significantly lower in the autistic group²⁸⁵ and, in individual cases, may be half the lower limit for age-matched controls.²⁸⁶ Plasma zinc is sub-normal in 40% of autistic children.²⁸⁷

Low zinc potentiates oxidative stress. In animals, zinc-deficient diets decrease total glutathione, vitamin E, GST, GPx, and SOD levels, while increasing lipid peroxides and free radicals in tissue, mitochondria, and cell membranes.^{288,289,290,291} In elderly adults, zinc supplementation decreases lipid peroxides.²⁹² In diabetics with retinopathy, zinc supplementation increases GPx and decreases lipid peroxides.²⁹³

Zinc status affects the intestine. Zinc deficiency in animals increases gastrointestinal NOS and susceptibility to gastrointestinal infection.²⁹⁴ Conversely, supplemental zinc decreases intestinal lipoxidation²⁹⁵ and lessens intestinal permeability.²⁹⁶

Clinicians increasingly appreciate zinc as a mainstay in the treatment of autism. William Walsh, who orga-

nized zinc and copper data on more than 3,500 autistic children at the Pfeiffer Treatment Center, finds that high doses of zinc (2–3 mg per kg body weight per day, of highly absorbable zinc picolinate) are often needed to achieve optimal behavioral response.²⁹⁷

Periodic measurement of plasma zinc is used to assure that zinc is not pushed above the normal laboratory range. Zinc is withheld on the day of testing to avoid artifacts. Zinc supplementation lowers copper, and this is usually desirable. Serum copper monitoring is used to avoid subnormal levels.²⁹⁸

Copper excess is evident in autism. Higher total serum copper,²⁹⁹ lower ceruloplasmin,³⁰⁰ and higher unbound copper in serum³⁰¹ are reported in autistic children. Copper, especially unbound, is highly pro-oxidant. Supplemental copper is rarely needed in autism, and even small doses of copper in supplements have been observed to produce negative behavioral effects.³⁰² Higher serum copper-to-plasma zinc ratios (in autism, mean 1.63 vs. 1.15 in controls, $p < 0.0001$),³⁰³ are correlated significantly with systemic oxidative stress in neurodegenerative disease.³⁰⁴ Sufficient zinc supplementation normalizes copper/zinc ratios.³⁰⁵

High zinc dosing can suppress manganese. A balancing dose of manganese, administered separately from zinc at dosages of approximately 5 mg manganese to 30 mg of zinc, is often beneficial, and serum manganese levels can be monitored to avoid excess.³⁰⁶

The antioxidant functions of zinc are prodigious. There are several important mechanisms:

- **Zinc protects SH (sulfhydryl) groups against oxidation**, as, for example, in the protection of the key antioxidant enzyme, GPx.³⁰⁷ The initial event in experimental zinc deficiency is loss of membrane SH groups, with consequent membrane fragility.³⁰⁸
- **Zinc competes with pro-oxidant metals such as copper and iron** for binding sites, preventing metal-catalyzed free-radical formation.³⁰⁹ Copper-containing enzymes are inherently prone to auto-oxidation, which is prevented by zinc.³¹⁰ Copper-induced membrane oxidation is prevented by zinc.³¹¹
- **Zinc is an essential constituent of copper-zinc SOD**, a key antioxidant enzyme. Even marginal zinc deficiency in humans decreases SOD activity.³¹² Zinc-deficient SOD becomes pro-oxidant, catalyzing biomolecular attack by ONOO[•].³¹³ Zinc-less SOD is neurotoxic.³¹⁴

- **Zinc induces the synthesis of metallothionein (MT)**,³¹⁵ an effective scavenger of free radicals (including ONOO[•])³¹⁶ and sequesterant for copper and other heavy metals.^{317,318} In animals, high-dose zinc induces measurably higher gastrointestinal MT levels.³¹⁹ Moderate zinc deficiency in animals, in which overt negative health effects are not manifest, is associated with significant reduction of retinal MT.³²⁰ MT normally increases as a protective response to oxidative stress, but actually decreases in response to oxidants when zinc is deficient.³²¹ MT also blocks copper toxicity, but this protective effect is lost in the presence of excess NO[•], which releases copper from MT, causing lipid peroxidation and apoptosis.³²² In the brain, MT_{III}, a neuronal growth inhibiting factor, is particularly sensitive to copper displacement by oxidants.³²³ This suggests a mechanism for reported greater gross brain size in younger autistic children.³²⁴
- **Zinc provides a physiological glutamate receptor blockade**,³²⁵ lessening excitotoxicity.
- **Diverse biomolecules are protected from oxidation by zinc**. By complexing with phospholipids,³²⁶ zinc blocks oxidation of fatty membranes.³²⁷ Zinc blocks peroxidation of polyunsaturated fat unbound to membrane.³²⁸ Zinc generally inhibits the oxidation of enzymes and other proteins,³²⁹ including those with functional SH groups vulnerable to mild oxidative conditions: Na,K-ATPase, Ca-ATPase, aquaporin, the voltage-gated calcium channel, and the NMDA-calcium channel.³³⁰

Future studies may establish that oxidative stress decreases clinical zinc retention. At a molecular level, oxidants (including NO[•]) displace zinc from proteins, including MT.^{331,332,333,334} This phenomenon may extrapolate to lesser whole-body zinc retention under greater oxidative stress. Schizophrenics have diminished urinary zinc loss in response to high doses of B6,³³⁵ possibly associated with antioxidant effects of B6.

Selenium

Mean red-cell selenium levels are lower in autistic children,³³⁶ and this may contribute to reported lower GPx in autism.^{337,338} As stated previously, GPx activity correlates with low-normal and borderline selenium levels.³³⁹ Clinicians frequently include oral selenium,

50–300 mcg/d, in nutritional supplementation for children with autism.

GPx is irreplaceable in the antioxidant defense, especially for protection of mitochondria, which do not contain catalase for protection from peroxide.³⁴⁰ In addition, GPx confers sole protection from organic hydroperoxides, which sustain the devastating lipoxidation chain reaction.^{341,342}

Lower GPx activity in frank selenium deficiency is associated with peroxidative damage and mitochondrial dysfunction.³⁴³ The physiological effects of selenium deficiency can be compensated partially by administration of vitamin E.³⁴⁴ GPx is sensitive to inactivation by copper³⁴⁵ and mercury.³⁴⁶ Human mercury exposure is associated with decreased GPx activity and increased lipid peroxides.³⁴⁷ In animals, GPx is protected by P5P³⁴⁸ and zinc supplementation.³⁴⁹

Lower GPx in autism favors greater membrane lipid peroxidation, which is known to impair receptor and enzyme functions, presumably due to conformational changes and altered binding.³⁵⁰ Lipid peroxidation has been shown to inhibit muscarinic, adrenergic, serotonergic, and insulin receptors, as well as Na,K-ATPase, and glutamine synthase.³⁵¹

Reduced Glutathione

In an open-label trial, daily intravenous GSH improved patients with early Parkinson's disease.³⁵² Likewise, intravenous GSH improves behavior in many autistic children, including very rapid extinction of perseverative behaviors such as hand-flapping. Rarely, apparent histamine-mediated reactions (sneezing, coughing, pruritic eyes) are noted.³⁵³

Oral GSH, up to 30 mg per kg body weight per day, has been beneficial in some children with cystic fibrosis, a high-oxidant state.³⁵⁴ The author finds similar doses of oral GSH helpful in some autistic children. Reversible adverse behavioral reactions to oral GSH have been reported in children with low plasma zinc levels. It is thought such GSH intolerance may result from rapid induction of metallothionein, which may deleteriously affect circulating zinc.³⁵⁵

Oral GSH is relatively well-absorbed. In animals, plasma GSH doubles within two hours of a large oral dose, mostly from absorption of intact GSH.³⁵⁶ Increased animal organ levels of GSH are attributed to absorption of intact GSH.³⁵⁷ In healthy humans, a 15

mg per kg oral dose of GSH increases plasma GSH levels two- to five-fold.³⁵⁸

High intestinal mucosal demand for GSH can exceed synthesizing capacity,³⁵⁹ as would be expected in an inflamed autistic gut. The intestinal mucosa imports intact GSH from both the intestinal lumen^{360,361} and the plasma³⁶² to combat oxidation. In normal physiology, biliary excretion of GSH represents a significant portion of total hepatic GSH production, and bile regularly bathes the intestinal mucosa with GSH.

Severe degeneration of the epithelium of the small intestine and colon, with mitochondrial swelling and degeneration, results from experimental GSH deficiency; these changes are prevented by the administration of oral GSH, which is associated with increased mucosal GSH levels.³⁶³ In animals, mucosal GSH levels increase rapidly and significantly after oral GSH, but less in the ileum than elsewhere.³⁶⁴ Oral GSH may lower oxidative stress in the autistic gut.

Strong *in vitro* antiviral properties of GSH are noted,³⁶⁵ and chronic viral infection in autism has not been ruled out.

An Oxidative Perspective on Newer Treatments for Autism

Subcutaneous vitamin B12 injections, as preservative-free methylcobalamin, 1250–7500 mcg weekly to daily, reportedly improve behavior in autistic children.³⁶⁶ One B12 intermediate, cob(I)alamin, is exquisitely sensitive to oxidative inactivation,³⁶⁷ so functional B12 deficiency may result from greater oxidative stress in autism.

NO• and nitrite elevations in autism should sound the “B12 alarm.” An intermediate form of B12 reacts specifically with NO•,^{368,369,370} and nitrite inactivates methylcobalamin.³⁷¹ NO• binds B12 to impair enzyme function, as with *in vivo* inhibition of methionine synthase by NO• at physiological concentrations.³⁷² Large parenteral doses of B12 are thought to scavenge and reverse the physiological effects of excess NO•.³⁷³

Oral folinic acid supplementation improves glutathione levels and GSH-to-GSSG ratios in autistic children.³⁷⁴ Tetrahydrofolate is very sensitive to oxidation,^{375,376} and degradation may be significant under conditions of greater oxidative stress.³⁷⁷ Folate deficiency (which may be aggravated by B12 impairment)

is known to decrease ATP levels and increase reactive oxygen species and excitotoxicity.³⁷⁸

Amino acid supplementation may be useful in autism. Plasma cysteine levels were much lower in a series of 286 supplement-naïve autistic children.³⁷⁹ Cysteine is produced endogenously from methionine, and provides a full third of the substituent molecules in glutathione and metallothionein.

Oral N-acetylcysteine (NAC), as a source of cysteine, is generally well-tolerated in autistic children, while direct supplementation with cysteine is not. Intravenous NAC (150–600 mg NAC + 1000–2000mg vitamin C + 1 ml sodium bicarbonate) treatments were reported to improve behavior in autistic children.³⁸⁰

The Pfeiffer Treatment Center follows generous zinc loading with a proprietary oral supplement³⁸¹ containing the amino acid constituents of MT. Initial data suggest that this formula increases levels of MT.³⁸² Some parents report improvement in autistic behavior coincident with greater exposure to natural sunlight. Ultraviolet radiation rapidly induces metallothionein,³⁸³ so sunlight may be of benefit if zinc is sufficient.

Thiamine tetrahydrofurfuryl disulfide (TTFD) via rectal suppository improved behavior and increased heavy metals clearance in autistic children.³⁸⁴ TTFD provides high cellular levels of thiamine, which boosts three mitochondrial enzymes known to be especially sensitive to oxidative stress.^{385,386} One of these, α -ketoglutarate dehydrogenase complex, is a rate limiter in energy metabolism and is inactivated by NO[•], both directly and via ONOO⁻.³⁸⁷

Casein- and gluten-free diets improved behavior in autistic children, possibly by reducing excess central opioid effects.³⁸⁸ Higher peripheral opioid peptides from casein and gluten are demonstrable in the urine of autistic patients,³⁸⁹ possibly due to oxidative inhibition of the enzyme needed to complete digestion of dietary casein and gluten.³⁹⁰ In addition, a shift towards oxidation in the redox environment is known to strengthen opioid binding, and GSH to weaken it.³⁹¹

Fatty acid supplementation has been found beneficial in autism.³⁹² Lower concentrations of highly-unsaturated fatty acids in plasma³⁹³ and red-cell membranes^{394,395} may be due to oxidative depletion of these key membrane building blocks and prostaglandin precursors. Depletion of omega-3 and omega-6 polyunsaturated fatty acids also is seen in schizophrenia, and these changes are associated with increased lipid peroxide levels.³⁹⁶

Eicosapentaenoic acid (EPA, an omega-3) was lower in the red-cell membranes of autistic children generally; arachidonic acid (AA, omega-6) was lower in the regressed subgroup.³⁹⁷ Fish oil, high in EPA, suppresses production of NO[•] and other free radicals^{398,399} and increases expression of GST and mitochondrial SOD.⁴⁰⁰ Brain levels of NO[•] and lipid peroxides are less in animals on diets supplemented with fish oil.⁴⁰¹

Administration of fish oil to even marginally B6-deficient animals can result in increased tissue lipid peroxide levels.⁴⁰² Prior administration of vitamin B6 and other antioxidants is suggested in autism, to avoid generation of toxic lipid peroxides.

Ongoing administration of fish oil to autistic children is associated with significant lowering of red-cell membrane dihomogamma-linolenic acid (DGLA).⁴⁰³ DGLA is an essential omega-6 precursor for prostaglandin-1, which tightens leaky gut and boosts immunity. Accordingly, autistic children receiving fish oil may benefit from a balancing dose of evening primrose oil, which provides gamma linolenic acid (GLA), a DGLA precursor.

Clinical and laboratory assessment helps titrate fatty acid dosing. After antioxidant loading, many autistic children do well on an initial dose of 3 grams fish oil and 1 gram evening primrose oil.⁴⁰⁴ Optimal doses vary individually, and over time.

Laboratory Assessment of Oxidative Stress

The use of oxidative biomarkers in the clinical management of autism is nascent. Various blood, urine, stool, and breath assays⁴⁰⁵ are potentially useful in determining optimal doses and combinations of nutrients and other interventions.

Some available assays include lipid peroxides, 4-hydroxynonenal (4-HNE), malondialdehyde (MDA), isoprostanes, levuglandin adducts, nitrotyrosine, oxidized nucleic acids, protein carbonyls, advanced glycation end products, cellular apoptosis, nutrient and antioxidant enzyme concentrations, total *nitrite* + *nitrate*, enzyme-binding affinities, and luminal NO[•] by rectal catheter. Ten-fold higher levels of neopterin,⁴⁰⁶ a marker for upregulation of NO[•] synthesis,⁴⁰⁷ suggest possible clinical utility of this measurement in autism.

In research, autistic brain and gut tissues certainly should be examined for specialized oxidative and nitrosative markers. Conventional pathologic assessment of

autistic brain tissue may not detect neuronal loss due to apoptosis, a marker for oxidative stress⁴⁰⁸ that can be obscured by rapid removal of apoptotic cells.⁴⁰⁹

Testing for Oxidative Biomarkers

Jointly, formal research and case-by-case testing by clinicians will determine the utility of oxidative biomarkers in the management of oxidative stress in autism. Potential assays vary in specificity, sensitivity, sample stability, and cost. Fundamentally, the most useful biomarkers will be those which best correlate with clinical improvement. Utility may vary among individual patients.

It is established that various blood fractions for GSH, GPx, and catalase are quite low in autism, and it is known that these parameters are affected by antioxidant treatments in other illnesses. Besides their more general usefulness, tissue concentrations of antioxidant nutrients (vitamins C, E, A; Zn, Mg, Se, fatty acids) or pro-oxidants (Cu, Fe, heavy metals) imply an oxidative diathesis. Cellular markers such as natural killer cytotoxicity or apoptosis may prove useful.

Non-invasive biomarkers are appealing. Breath-testing for ethane and pentane are limited presently to research. DNA-adducts in urine are available commercially, but have not been measured systematically in autism. Pre-publication data from two studies indicate that urinary isoprostanes are much higher in autism; these are more stable than lipid peroxides, and less prone to artifact from fats ingested prior to collection.

By survey, we identified a commercial American laboratory—BioHealth Diagnostics—that offers urinary isoprostane testing. Simultaneous measurement of urinary creatinine improves accuracy of urinary isoprostane assay. A number of progressive commercial laboratories (Great Smokies, Great Plains, Immunosciences, Metamatrix, Vitamin Diagnostics) measure the various oxidative biomarkers, including indirect assessment of hydroxyl radical production and energy profiling by urinary organic acid analysis.

Future Directions

Leading thinkers are now giving serious consideration to the potential significance of greater oxidative stress in autism. If oxidative stress proves important in autism, there are many implications. For instance, nutritional management of autism⁴¹⁰ to modulate oxidative stress would presumably gain importance.

We may need to reconsider ingrained living habits. Consumption of free radicals via foods fried in polyunsaturated oils⁴¹¹ may need to be curbed. Ingestion of excitotoxic flavor enhancers, chlorine, nitrite, nitrate, and copper in water may need reassessment. Pro-oxidant^{412,413,414} and antioxidant^{415,416,417,418} drug profiles may become more pertinent.

We may need to consider how oxidative influences during pregnancy can affect neurodevelopment, including post-partum development. Gestational zinc deficiency, for instance, produces oxidative DNA damage in newborn primates.⁴¹⁹ The ubiquitous flavor enhancer and excitotoxin MSG traverses the placenta and causes fetal neurotoxicity in rodents.⁴²⁰

Higher NO• is now a well-established fact of autism that may provide clues to specific etiologies, aggravants, and treatments. Viral infections can greatly increase NO• production in brain and other tissues, so high NO• in autism should increase the demand for a systematic examination of autistic tissues for viral antigen.

Higher NO• in autism might focus useful attention on treatment with antioxidants with specificity for NO•. Vitamin C is a good NO• quencher,⁴²¹ and so are melatonin and uric acid. Melatonin effectively scavenges both NO• and ONOO⁻.⁴²² Melatonin has excellent potential for relief of oxidative stress in both brain and gut,^{423,424} increases expression of GPx,⁴²⁵ and has proved effective in autistic sleep disorders.⁴²⁶

Uric acid normally represents up to 60% of total plasma antioxidant capacity.⁴²⁷ It effectively binds transition metals and reactive species, and is especially effective at quenching NO•⁴²⁸ and ONOO⁻.⁴²⁹ Careful upward titration of uric acid levels with oral inosine, a uric acid precursor, may be of benefit in high-NO• states such as multiple sclerosis⁴³⁰ and autism.

Testing and treating mitochondrial function to improve energy production probably merits a higher priority in autism. Acetyl-L-carnitine (ALC) and α -lipoic acid (ALA) enhance mitochondrial function and reduce oxidative stress in senescent animals.⁴³¹ Oral administration of the mitochondrial metabolite L-carnitine has improved behavior in children with Rett syndrome,⁴³² and initial trials of high carnitine doses in autism are underway.

A leading university clinic often treats patients referred for suspected mitochondrial disease with a combination of CoQ10, vitamin E, and balanced B vitamins.⁴³³ CoQ10, in combination or alone, is an attractive potential intervention in autism. It facilitates ATP production by carrying electrons and protons in the electron transport chain, and also acts in its reduced form to protect mitochondria by quenching oxidants.⁴³⁴ Vitamin B3 is crucial to mitochondrial energy production and effective in the high-oxidative state of schizophrenia,⁴³⁵ but has received little attention in autism.

Many key biochemical functions are sensitive to oxidative impairment (Table 30.8). We need to examine systematically the functions of the enzymes, receptors, G-proteins, and vitamin cofactors in autism, and integrate findings into clinical management. Glucose-6-phosphate dehydrogenase (G-6-PD) activity, given its central role in the reduction of GSH, is but one of many oxidant-sensitive functions that deserve scrutiny. We should not be surprised to encounter a very broad enzymopathy in autism.

Table 30.8 Sensitive to Oxidative or Nitrosative Impairment

Enzyme or Cofactor	Reference
Glutamic acid decarboxylase	215
Glutamate transporter	217
Glutamine synthetase	216, 351
GABA channels	105
B6 vitamers	273, 274, 275
Pyridoxal kinase by carbonyl inhibition	261
B6-dependent enzymes by carbonyl inhibition	437
Tetrahydrofolate	371, 376
Methionine synthase	438
B12 vitamers	367, 368, 369, 370, 371
Glucose-6-phosphate dehydrogenase	439
CoenzymeA	208
α -KGDHC	239, 386, 388
Na,K-ATPase, Ca^{++} Channels, Aquaporin	308, 351
Catalase	440
Glutathione peroxidase	271

Summary

The evidence strongly supports the presence of greater oxidative stress in autism. The clinical response to antioxidant nutrients also suggests that increased oxidative stress does affect the expression of autistic symptoms. The important issues surrounding this topic are (a) how oxidative stress creates these effects, and (b) what are the most effective therapeutic interventions.

Antioxidant therapeutic trials measuring oxidative biomarkers could help elucidate the mechanisms. While such research is progressing, clinicians and parents are advised to implement safe nutritional interventions—sooner, rather than later. It is also time to start applying laboratory biomarkers for oxidative stress to optimize doses and combinations of nutrients.

The preliminary lipofuscin data are potentially very important, and replicative and expansive studies are indicated. It is conceivable that lipofuscin analysis might identify specific toxic or infectious etiologies. Greater lipofuscin in the autistic brain is a concrete suggestion that neurodevelopment in autism is altered by oxidative influences.

By analogy, chronic neonatal vitamin E deficiency may help us understand how excess oxidative stress in early life can indeed affect neurodevelopment. Vitamin E deficiency is a neurological disease that clearly results from low antioxidant protection from birth.^{436,437} Lipofuscin deposition is prominent. Neurological symptoms—gait disturbance, abnormal ocular movements—present at 18–24 months,⁴³⁸ are a common chronology in autistic regression.

Beyond analogy, we simply might consider the clinical potential of vitamin E in autism, or in ostensibly healthy children prior to regression. Besides enteropathy, autistic children demonstrate an immune profile very similar to common variable immune deficiency (CVID).⁴³⁹ Neurological complications of vitamin E deficiency are seen in patients with CVID and enteropathy, and vitamin E screening has been recommended for patients with these conditions.⁴⁴⁰ Preliminary data suggest lower plasma vitamin E levels in autistic children,⁴⁴¹ and functional testing by red-cell hemolysis may be even more sensitive.

Optimistically, we note that oxidative damage to biomolecules is not always permanent. Oxidative inactivation of enzymes, for instance, is reversed when sufficient

antioxidant is provided.⁴⁴² Even structural elements such as the cytoskeleton can undergo restoration by GSH.⁴⁴³

If we learn that oxidative stress is an important mechanism in autism, then our search for genetic and environmental causes gains focus. A spatial or chronological map of oxidative changes in the autistic brain may conform to the effects of one or more toxins. Lipofuscin may contain an etiologic agent. Perhaps an efficient approach to genetic research should prioritize the examination of genes affecting autism that may also be relevant to oxidative stress. From the oxidative wounds, science may more rapidly deduce the causes, treatments, and prevention of autism.

Oxidative Stress and Glycemic Control

Dan Lukaczer, ND

Introduction

Type 2 diabetes (T2D) is a chronic, progressive disease that is becoming increasingly common throughout much of the world, with the incidence rising most rapidly among younger people. With the epidemic explosion of T2D in the United States, glycemic control has become an increasingly important clinical issue. Hyperglycemia, an inevitable consequence of T2D, is the source of most of the deleterious effects usually associated with this disease. Hyperglycemia leads to generation of free radicals or reactive oxygen species (ROS), a state known as oxidative stress. There is strong evidence that this oxidative stress is at least partly responsible for the development or exacerbation of insulin resistance during diabetes,⁴⁴⁴ and for the complications, morbidity, and mortality associated with diabetes.⁴⁴⁵ The body's defenses against oxidative stress (discussed in detail earlier in this chapter) are accomplished by an interconnecting system of endogenous antioxidant micronutrients, phytonutrients, and enzymes.⁴⁴⁶ T2D is associated not only with increased ROS, but in many instances with a reduction in these antioxidant defenses as well.

We review in Chapters 19 and 34, respectively, glucose dysregulation and its many manifestations, and a practical clinical approach to the diagnosis and treatment of insulin resistance. Here we will focus specifically on an approach to controlling the oxidative stress that can often accompany this dysregulation. While

clearly overlapping, it is important to understand T2D from this standpoint as well.

It is well established that tight glycemic control is the most effective way of preventing or decreasing diabetic complications. However, supplementation with antioxidant micronutrients has been proposed as an important adjunctive therapy. In a comprehensive review of oxidative stress and the use of antioxidants in diabetes in 2005, Johansen et al.⁴⁴⁷ point out some of the problems with the evidence base on this topic: most of the studies have been done on animals, each one examining only a small part of the underlying mechanisms involved in the overall process; very few antioxidants have been studied in depth (primarily studied have been vitamins C and E and alpha-lipoic acid); the majority of clinical trials were not designed to study diabetic patients specifically; and "none of the studies to date effectively assessed the baseline oxidative stress of the enrolled patients using any of the commonly accepted markers of inflammation." Given all of these caveats, we nonetheless feel that the high level of oxidative stress present in diabetics warrants a review of the current evidence, and a judicious application of that evidence by clinicians.

The Link between Oxidative Stress and Glycemic Control

T2D is characterized by an increased risk for the development of macrovascular disease (coronary heart disease, cerebrovascular disease, and peripheral vascular disease) and microvascular complications (diabetic retinopathy, nephropathy, and peripheral neuropathy). Cardiovascular (CV) complications are the leading cause of mortality and morbidity in T2D.⁴⁴⁸ Additionally, there is a strong relationship between poor glycemic control and the progression of diabetic complications such as retinopathy and polyneuropathy.⁴⁴⁹

Clearly, frank diabetes carries the most risk; however, the development of CV complications does not end precisely at the boundary of defined hyperglycemia. Even mild increases in blood sugar (referred to as impaired glucose tolerance) can contribute to microvascular injury, atherosclerotic changes, and cardiovascular disease.⁴⁵⁰ It is clear that the progressive relationship between glucose levels and cardiovascular risk extends well below the diabetic threshold.⁴⁵¹

While the mechanisms by which hyperglycemia produces these complications are complex and not completely understood, much evidence points to the association between hyperglycemia and increased oxidative stress.⁴⁵² Blood glucose control and vascular complications affect both free radical indices and antioxidant status in T2D patients.⁴⁵³ In addition, many endothelial functions can be affected by ROS and oxidative stress (and may be ameliorated by exogenous antioxidants).⁴⁵⁴

Two primary mechanisms by which hyperglycemia promotes the generation of ROS are activation of the polyol pathway and increased glucose auto-oxidation. Reactive oxygen species affect vascular smooth muscle cell growth, migration, and endothelial function.⁴⁵⁵ Elevated levels of ROS can also cause general damage to proteins through cross-linking, fragmentation, and lipid oxidation. Radical-generating reactions cause formation of advanced glycation end products (AGEs) due to elevated nonenzymatic glycation of proteins, lipids, and nucleic acids. Once formed, AGEs can influence cellular function by attaching to various binding sites. Binding of AGEs can result in the generation of intracellular oxidative stress and subsequent activation of NFκB.⁴⁵⁶ Additionally, there is specific evidence that in chronic hyperglycemia, apoptosis induced by oxidative stress causes reduction of beta-cell mass.⁴⁵⁷ Overall, there is sufficient human and animal research to support the hypothesis that hyperglycemia results in increased oxidative stress and increased formation of advanced glycation end products.⁴⁵⁸ There is also evidence that hyperinsulinemia, in the face of normal to near-normal glucose levels, may enhance free radical generation and thus contribute to oxidative stress as well.⁴⁵⁹ Elevated insulin itself may inhibit proper metabolism of fatty acids, promoting the proinflammatory arachidonic acid cascade and resulting in increased free radical generation and oxidative stress.⁴⁶⁰

Hyperglycemia and Antioxidants

The body possesses defense mechanisms that, in the healthy individual, adequately control ROS concentrations under most conditions. In T2D, however, increased ROS generation results in increased oxidative stress, which in turn can lead to many of the hallmark complications of the disease. Reduction of oxidative stress is therefore an important goal for management of this condition. As discussed earlier in this chapter, antioxidant

nutrients may help to reduce oxidative stress. In various studies of humans and animals, dietary supplementation with antioxidants is associated with decreased risk of T2D and induces changes that can be beneficial in reducing insulin resistance and protecting various tissues from injury.⁴⁶¹ Below is a review of certain antioxidants that may be of particular importance.

Lipoic Acid

Some of the most convincing evidence for a beneficial effect of antioxidant therapy in diabetes has been done on lipoic acid,^{462,463,464} which is a potent lipophilic free radical scavenger. Since oxidative stress appears to play an important role in the pathogenesis of diabetic neuropathy, it is important to consider the benefits of lipoic acid in this condition. Several clinical studies reveal that lipoic acid is generally safe and effective in reducing symptoms of diabetic peripheral neuropathy. Doses of 600–1200 mg/d of ALA may improve microcirculation and diabetic polyneuropathy.^{465,466} Oral treatment for 4–7 months tended to reduce neuropathic deficits and improve cardiac autonomic neuropathy.⁴⁶⁷ Oral treatment also decreased urinary albumin excretion after 18 months, suggesting that the antioxidative effects of alpha-lipoic acid may play a promising role in the pathogenesis of diabetic nephropathy as well.⁴⁶⁸ In a 2004 double-blind study, 600 mg of intravenous ALA rapidly and significantly improved neuropathic sensory symptoms.⁴⁶⁹

Vitamins

Studies of vitamin E have produced conflicting results. In an animal model, vitamin E supplementation significantly improved glycemic control, possibly by minimizing free radical damage to the pancreatic β-cells.⁴⁷⁰ In humans, a low plasma vitamin E concentration was associated with a 3.9-fold increased risk of incident diabetes.⁴⁷¹ Vitamin E may reduce LDL-cholesterol oxidation and therefore may decrease cardiovascular risk in T2D.⁴⁷² However, not all human studies have been positive. For instance, the Heart Outcomes Prevention Study, using a dose of 400 IU/day of d-alpha-tocopherol, did not show improvement in microvascular or cardiovascular damage.⁴⁷³ Overall, human studies with vitamin E have been mixed.⁴⁷⁴

Similarly, studies of vitamin C have shown positive effects, negative effects, and no effects, depending on

the parameters (and subjects) being studied. When administered alone or in combination with vitamin E, vitamin C has been shown to lower oxidative stress parameters in diabetic animals.^{475,476} Supplementation with vitamin C and/or E in animal models has been shown to modulate late pathological changes in the retina and peripheral nerves.^{477,478,479} Two grams/day of vitamin C demonstrated a beneficial effect on both glycemic control and blood lipids in T2D subjects.⁴⁸⁰ In another 1995 study, the percent increase in plasma vitamin C levels was correlated with the percent decline in plasma free radicals.⁴⁸¹ A 2002 study demonstrated that 1.25 g of vitamin C and 680 IU of vitamin E significantly lowered urinary albumin excretion rate, a marker of progression to end-stage renal disease.⁴⁸² One gram of vitamin C alone lowered the urinary albumin excretion in diabetic subjects,⁴⁸³ but the same dose in a study of effects on microcirculation in T2D patients found no effect on microvascular reactivity, and no effect on inflammatory cytokines or ox-LDL.⁴⁸⁴ Doses of 100 or 600 mg/d of vitamin C reduced sorbitol accumulation and therefore may be useful in preventing diabetic retinopathy complications.⁴⁸⁵ On the other hand, a 2004 study⁴⁸⁶ concluded that “high vitamin C intake from supplements is associated with an increased risk of cardiovascular disease mortality in postmenopausal women with diabetes.” Interestingly, increased vitamin C from dietary changes did not show a similar pattern.

Riboflavin is an antioxidant that regenerates glutathione, which plays a major role in the detoxification of ROS. Riboflavin deficiency has been noted in T2D, but little interventional work has been done with this nutrient.

Minerals

Zinc and selenium have been shown to improve certain aspects of the oxidative stress of T2D. Selenium acts as a coenzyme in glutathione peroxidase (GPx) activity. It has been suggested that selenium, through its effect on GPx, may decrease NFκB activity, which has been associated with hyperglycemia and oxidative stress.⁴⁸⁷ Selenium supplementation to diabetic rats prevents not only oxidative stress but renal structural injury as well, suggesting that selenium plays a role in reducing the oxidative stress associated with diabetes.^{488,489} Human studies have also shown positive results in oxidative stress markers following selenium supplementation.⁴⁹⁰

Zinc is bound to insulin and stabilizes the molecule; decreased zinc uptake may be one of the features of diabetic patients.⁴⁹¹ Zinc supplementation has been shown to increase glucose disposal,⁴⁹² and a study of skeletal muscle cells indicated a positive effect on insulin signaling leading to glucose uptake.⁴⁹³ Zinc depletion appeared to increase the susceptibility of insulin to free radicals, and it has been suggested that zinc is protective against free radical injury.^{494,495} Supplementation with zinc may decrease antioxidant damage.⁴⁹⁶

Vanadium appears to exhibit antioxidant properties.⁴⁹⁷ However, vanadium can become toxic and even a pro-oxidant at high levels.^{498,499} Copper and manganese are both cofactors in superoxide dismutase. This suggests a physiological role for these nutrients as antioxidants in T2D. However, little work has been done with these nutrients to validate their usefulness.

Taurine, CoQ10, and Other Accessory Nutrients

Taurine and coenzyme Q10 are endogenous antioxidants that, while not essential nutrients, may be beneficial in T2D at higher levels. In rats with diabetes induced by chemical destruction of β-cells, taurine supplementation reduced renal oxidant injury by decreasing lipid peroxidation and inhibiting the accumulation of advanced glycation end products within the kidney.⁵⁰⁰ The effects of oral treatment with coenzyme Q10 (60 mg twice daily) were examined in a randomized, double-blind trial of 30 patients with coronary heart disease. After eight weeks, the treatment group receiving coenzyme Q10 had reduced plasma levels of insulin (fasting and 2-hr), glucose, and lipid peroxides as compared to the control group.⁵⁰¹ In another trial, 200 mg of CoQ10 daily improved HA1C and blood pressure in T2D patients, but there did not appear to be a specific antioxidant effect that could be measured by the plasma levels of isoprostanes (markers of oxidative stress).⁵⁰² Results overall with CoQ10 are inconsistent,⁵⁰³ but a 2004 review did conclude that CoQ10 might “improve endothelial dysfunction by ‘recoupling’ eNOS and mitochondrial oxidative phosphorylation.”⁵⁰⁴

Other antioxidant phytonutrients have been reported to be beneficial. Dietary flavonoids such as catechins and quercetin may protect against oxidative stress in T2D.⁵⁰⁵ *In vitro* and animal studies have shown that catechins in particular may help as antioxidants in protection of pancreatic beta cells.^{506,507,508}

Summary

While there is still controversy over the role of anti-oxidants and oxidative stress in T2D, there appears to be sufficient evidence to show that oxidative stress in the diabetic patient is greater than normal antioxidant defenses can withstand; and this increased oxidative stress is associated with the onset and progression of diabetic complications. Overall, but by no means unambiguously, results indicate that dietary supplementation with micronutrients may be a complement to conventional therapies for preventing and treating diabetes and its complications.⁵⁰⁹ It seems likely that oxidative stress is only one factor contributing to diabetic complications; thus, antioxidant treatment would most likely be more effective if it were coupled with other treatments. While supplementation is expected to be more effective when a deficiency in these micronutrients exists, studies have reported beneficial effects in individuals without deficiencies. Some of these positive studies were short term and had small sample sizes, but there are other, placebo-controlled, multicenter trials that have shown significant improvements in diabetic complications by addressing the oxidative stress component of diabetes. Treatment with antioxidants has been demonstrated to preserve beta-cell function, protect the vascular endothelium, and ameliorate polyneuropathy, retinopathy, and nephropathy. Results of these reviewed studies, and others, indicate that dietary supplementation with antioxidant nutrients may be a safe and simple complement to conventional therapies for preventing and treating diabetic complications. (Practitioners should also remember that dietary interventions to increase consumption of antioxidants have few safety problems, may produce an improvement in redox status parameters,⁵¹⁰ and undoubtedly produce significant other benefits as well, as discussed in many other chapters of this book.)

- ▶ *Systemic In-office Detoxification*
- ▶ *Home-based Detoxification*
- ▶ *The Gut-Liver Axis*

Genetic and Environmental Influences on Detoxification

Michael Lyon, MD, Jeffrey S. Bland, PhD, and David S. Jones, MD

In Chapter 22, the basic mechanisms and potential dysfunctions of detoxification and biotransformation were presented in detail. In this chapter, we will review some of those elements from a more clinical perspective. This initial part of the chapter provides a comprehensive overview of detoxification/biotransformation issues, followed by two examples of specific clinical protocols for detoxification—one for in-office use under the clinician's supervision, and the other for in-home use by patients—and ending with an in-depth discussion of the gut-liver connections (and the clinical implications of those relationships for this topic).

Introduction

Throughout evolution, we have developed complex protection systems against endogenous and exogenous substances. Scientists working in the early 1970s discovered the first enzyme of the detoxification family. This enzyme contained iron and emitted absorbed ultraviolet radiation of 450 nanometers, so it was called a cytochrome P450. A high level of this cytochrome P450 enzyme was found to be localized in the liver, and researchers soon discovered it was responsible for converting lipophilic (fat-loving) toxins into bio-trans-

formed intermediates that were more water-soluble (*phase I detoxification*).

Later research revealed that most of these biotransformed intermediates undergo further biotransformation in the liver by a second series of enzymes called conjugases. They called this *phase II detoxification*. The conjugases were enzymes that attached molecules to the biotransformed intermediate, such as glucuronic acid, sulfate, glutathione, glycine, taurine, or methyl groups. Hormones and other signaling molecules are detoxified (biotransformed) and eliminated through specific phase I and phase II processes. The most common phase II pathways include sulfation, glucuronidation, and methylation. Drugs and xenobiotics, along with hormones and other endogenous metabolites, compete for these same detoxification pathways and specific phase I enzymes. As research continued into the 1980s and 1990s, investigators discovered a tremendous number of phase I cytochrome P450s and phase II conjugases. We now know that phase I cytochrome P450s are members of a “super-family” of enzymes,¹ for which more than 58 different genes exist in humans.

Genetic Variability in Detoxification Function

The complexity of detoxification and biotransformation is intensified by the widespread genetic polymorphisms for the expression of cytochrome P450 enzymes within the human species. Researchers have discovered that great variability exists among humans in not only the structure and function of the phase I cytochrome P450s but the phase II conjugases as well.² Recent molecular genetic analysis has identified hundreds of single nucleotide polymorphisms (SNPs) that modify the structure and function of the various detoxification enzymes. As a consequence of this inter-individual variation in detoxification enzyme function, very significant differences exist from person to person in the way we metabolize specific substances. (This material was covered in detail in Chapter 22.)

The full extent and significance of this phenomenon have not been completely ascertained, and there is no strong consensus in the literature about specific relationships, but a number of studies have suggested a correlation between genetic deficiency of certain cytochrome P450 enzymes and susceptibility to environmentally mediated disorders.^{3,4,5,6,7} Early cancer indications, for example, have not always been reproducible, particularly lung cancer and prostate cancer.⁸ In a 2003 review, Guengerich⁹ observed that “Difficulties in studying the association of cancers with toxic chemicals in the environment are made more complex by the usually very limited numbers of patients available, the need to identify individual chemicals and levels of exposure, and the long latency period (up to 20 years) from exposure to onset of cancer.”

These differences in the metabolism of drugs are not only genetic; they also relate to environmental and nutritional influences that modify gene expression and proteomic activity of the cytochrome P450 and conjugase family of enzymes. We are now aware that dietary factors can play a significant role in modifying first-pass detoxification or biotransformation in an individual by inducing or inhibiting transport and metabolism.¹⁰

The majority of the research in this area presents epidemiological, animal-based, basic science, small human clinical trials, or case-based information. As a consequence, it is difficult to recommend with certainty specific patient intervention techniques from the literature. Given, however, that patients and practitioners alike have increasing concerns about environmentally-

related illnesses, we believe it is important to explore the role that diet and lifestyle may play in prevention, risk reduction, and therapeutics. The concepts described in this chapter frame an important component of the functional medicine model.

Genetics of Detoxification and the Diet

Heritable polymorphisms are also known for several conjugating enzymes (phase II detoxification) that are extensively involved in the metabolism of exogenous chemicals,¹¹ a significant factor conferring susceptibility to environmental toxins. An example of this genetic variation is the activation of glutathione S-transferase (GST), an important phase II detoxification enzyme involved in glutathione conjugation.¹² There are a number of polymorphisms of GST, including those within the *mu* and *theta* classes (GSTM and GSTT).

Certain foods may contain constituents that activate the expression of a specific detoxification process, while other foods may contain substances that inhibit its activity. For example, in humans, consumption of Brussels sprouts leads to the induction of one isoform of glutathione-S-transferase only, and the administration of the terpene eugenol from thyme oil inhibits the activity of two different isoforms of glutathione-S-transferase at the same time.¹³ Studies of the induction of individual isozymes of glutathione transferase in humans have shown that Brussels sprouts and garlic induce these activities in similar ways.

The findings that food/drug interactions are associated with alterations in the detoxification of hormones have important clinical implications. Foods may interact with hormones during key metabolic processes:

1. before and during gastrointestinal absorption,
2. during distribution,
3. during metabolism, and
4. during elimination.¹⁴

Specific macro- and micronutrients in foods may influence the biotransformation process of both phase I and phase II enzyme systems, and thus have an impact on all four of these fundamental physiological processes. For example, nondigestible carbohydrate (fiber) that is not digested in the intestinal tract may be quite bioactive toward the detoxification enzyme systems. The most important effects of food on biotransformation and its relationship to detoxification are observed

through the influence on metabolism and elimination of various substances.

Influencing Detoxification

Phytochemicals

Dr. Paul Talalay and his colleagues from the Johns Hopkins University School of Medicine have been working for the past 40 years to elucidate the mechanisms by which various phytochemicals in plant foods modify the activity of phase I and phase II enzyme systems.^{15,16} Animal studies reveal that a surprising number of phytochemicals protect rodents against neoplastic, mutagenic, and other toxic effects when the animals are exposed to various types of carcinogens. Dr. Talalay points out that these chemoprotective agents often belong to totally unrelated chemical classes, such as substituted phenols, coumarins, sulfur compounds such as isothiocyanates, flavones, indoles, retinoids, tocopherols, and selenium compounds.¹⁷

Specific chemical substances in various foods have specific effects on the expression and activity of the biotransformational detoxification system. For many years, we have known, in general, that certain foods seemed to promote improved detoxification. As a consequence of the work of Talalay and others, however, we now know that certain phytochemicals have specific influences on the various isoforms of cytochrome P450 and the variety of conjugases involved with phase II activity.¹⁸

The discovery that specific phytochemicals influence the activity of different components of the phase I and phase II biotransformational detoxification system poses a challenge to the clinician concerning what specific foods or phytonutrients to recommend to improve the unique detoxification systems of individual patients. Upregulation of the activity of phase I cytochrome P450, without proper balance with phase II detoxification capability, can result in a more harmful outcome by producing higher levels of highly reactive biotransformed intermediates. The clinical focus should not be solely on inducing increased detoxification activity, but rather on trying to establish balance in the patient between phase I and phase II detoxification systems.

Mono- and Multifunctional Modulators of Detoxification

The challenge of finding the appropriate clinical support program to balance phase I and phase II detoxification systems was simplified by Talalay's discovery of specific phytochemicals that are bifunctional modulators of detoxification effects. These phytochemicals have an influence on modulating specific phase I cytochrome P450s and phase II conjugases simultaneously, thereby leading, potentially, to balanced detoxification.¹⁹ Some agents act in a monofunctional manner. They have only single effects on either cytochrome P450 isoforms or phase II conjugases.

The impact of any factor upon detoxification status is the sum of all effects upon phase I and phase II enzyme systems. For example, moderately high-protein diets bring about upregulation of P450s in a pattern that may either increase or decrease susceptibility to pesticides and other xenobiotics, depending upon whether the protein is of animal or vegetable origin, while diets that are deficient in protein may increase pesticide toxicity because of P450 downregulation. On the other hand, cigarette smoking brings about a monofunctional induction of P450, biotransforming certain xenobiotics into potent carcinogens while simultaneously increasing oxidative stress.²⁰

Numerous phytochemicals are known to exert potent effects upon both phase I and phase II enzyme activities. With few exceptions (such as grapefruit slowing drug metabolism, or St. John's wort accelerating drug metabolism), plant foods common to the human diet have been shown to have important effects upon detoxification systems. Onions and garlic, cruciferous vegetables, chlorophyll, terpenoids (e.g., citrus, *Ginkgo biloba*, menthol, camphor), bioflavonoids (e.g., citrus, pine bark, grape seed, green tea) and others all act in a complex, highly beneficial manner to improve balanced detoxification capability.²¹

In a landmark article titled "Dietary Carcinogens and Anti-carcinogens," Ames explained that although some foods are known to contain substances that may be potential carcinogens, whole foods, particularly those in the vegetable family, contain phytochemicals that modulate the potential carcinogenic activity of other substances through their ability to modify detoxification.²² Further evidence indicates this bifunctional aspect of

various phytochemicals is important in establishing a higher degree of tolerance and safety in their influence on hepatic bifunctional detoxification systems.

A diet rich in bifunctional modulators, as well as monofunctional phase II regulators, influences the detoxification and elimination of neuroendocrine modulators. According to research by Lanai et al., “Compounds acting as inducers of anti-carcinogenic enzymes are divided into two classes: (1) bifunctional inducers, which induce those phase I xenobiotic-metabolizing enzymes ... and subsequently generate intermediates which transcriptionally activate genes encoding phase II enzymes including QR (quinone reductase); and (2) mono-functional inducers, which induce phase II enzymes directly without inducing the phase I enzymes.”²³

Talalay pointed out that protection against endogenous and exogenous toxins is achieved through the proper balance between monofunctional inducers of the selective phase II enzymes and appropriate bifunctional inducers that help regulate both phase I and phase II activities, resulting in “balanced detoxification.”²⁴

Monofunctional and Bifunctional Inducers and Cancer Risk

Dr. Johanna Lampe and her colleagues at the Fred Hutchinson Cancer Research Center in Seattle, Washington, have been actively involved in clinical evaluation of these concepts in studies of human patients. In one paper, Dr. Lampe discusses the effects of genetic polymorphisms on detoxification systems and the role of specific diets rich in phase II monofunctional and bifunctional inducers in reducing carcinogenic risk.²⁵ According to Dr. Lampe, a diet/gene interaction that works through the detoxification mechanisms is likely to contribute significantly to the observed inter-individual variations in cancer risk in response to exposures to various carcinogens. Her work once again emphasizes the importance of supporting balanced detoxification through proper activity of both phase I cytochrome P450s and phase II conjugases.

Phase II enzymes, such as glutathione-S-transferase, N-acetyltransferase, sulfotransferase, UDP-glucuronosyltransferase, and catechol-methyl transferase, are extra-ordinarily important in providing balanced detoxification. Upregulation of phase I cytochrome P450 without a concomitant balance with phase II

enzymes can result in significant increase in reactive intermediary metabolites, which may increase the risk of cellular injury. The scheme that relates to the balance between phase I and phase II detoxification enzymes is shown in Figure 31.1. (Another version can be seen in Figure 22.1, in Chapter 22.)

Glucuronidation

Dr. Lampe has focused on the role of specific nutrients in the regulation of phase II glucuronidation. Glucuronidation is a major detoxification process catalyzed by UDP glucuronosyltransferases that convert a vast variety of endogenous compounds, including bilirubin, steroid and thyroid hormones, and retinoids or bile acids, as well as a remarkable number of lipophilic xenobiotics, into more hydrophilic and therefore excretable metabolites.

UDP glucuronosyltransferase enzymes are members of a super-family of enzymes with considerable genetic polymorphisms. Individuals who have specific polymorphisms in specific UDP glucuronosyltransferases are more susceptible than others to Gilbert's syndrome. Reduced glucuronidation ability of specific substances in these individuals may make them more susceptible to the effects of endo- and exotoxins.²⁶ Glucuronidation is under dual regulatory control. The first control, carried out on the genetic expression level of the isoenzymes, determines the amount of a different isoform available. The second control is modulation of the activity of individual isoforms to their “functional state” by specific substances, including certain nutrients.²⁷

Individual differences in glucuronidation ability.

Lampe et al. discovered that UDP glucuronosyltransferase polymorphisms result in significant differences in glucuronidation ability from person to person, and that dietary factors may significantly influence the activity of the phase II biotransformation function.²⁸ Interestingly, Dr. Lampe has found considerable differences in the activity of UDP glucuronosyltransferase isoforms between Caucasians and individuals of Asian ethnicity, suggesting the origin of possible differences in certain disease incidence upon exposure to various toxins.²⁹

Figure 31.1 Interrelationships among the biotransformation enzyme systems

In a pilot study, Lampe found the consumption of different vegetables, including members of the allium (garlic and onion), apiaceae (carrot), and cruciferous (broccoli and Brussels sprouts) families had different influences on phase II GST enzyme activity.³⁰ In another study, researchers found that garden cress, a relative of the cruciferous vegetables, contains specific glucosinolates that increase glucuronidation activity. According to the authors of this study, “Our findings suggest that the chemoprotective effect of GC (garden cress) is mediated through enhancement of detoxification of IQ (2-amino-3-methyl-imidazo [4,5-1] quinoline by UDPGT.”³¹

Once again, these studies demonstrate the important concept that clinical response in biotransformation is a result of genomically determined factors and environ-

mental influences on gene and protein expression. The clinical application of this emerging information is to find dietary programs containing the right balance of monofunctional inducers of phase II enzymes and bifunctional inducers of the appropriate isoforms of phase I and phase II enzymes to provide balanced detoxification in the majority of genotypes represented in a genomically heterogeneous population such as that in the United States.

Factors that induce glucuronidation. With specific reference to UDP glucuronosyltransferase induction, researchers have demonstrated that a number of flavonoids have the ability to induce specific glucuronidases, which will increase glucuronidation. Luteolin is one example of a flavonoid that can induce glucuronidation; another is chrysin, which induces UGT1A1.³²

Thyroid hormone T_3 is also involved in the expression of UGT1A1 and UGT1A6. UGT1A1 is responsible for the glucuronidation of bilirubin, while UGT1A6 is responsible for the glucuronidation of potentially xenobiotic phenolic compounds. The influence of T_3 on UGT expression was also found to depend on vitamin A retinol status. A deficiency of vitamin A resulted in inhibition of the expression of UGT1A1 and 1A6, even in the absence of administered T_3 . The investigators conclude, "Our results demonstrate for the first time the existence of a strong interaction between vitamin A and thyroid hormone on the regulation of genes encoding cellular detoxification enzymes, in this case the UGT."³³

The role of dietary fiber in glucuronidation. It has also been found that certain sources of dietary fiber will influence the activity of UDP-glucuronosyltransferase. A comparative study of various forms of fiber in animals found that intestinal microflora played a key role in the effects of fiber on xenobiotic-metabolizing enzyme systems, not just as a consequence of bacterial fermentation of various types of fiber. In examining wheat bran, carrot, cocoa, and oat bran fibers and their influence as potential modulators of detoxification, researchers found that cocoa fiber seemed to influence phase II UDP glucuronosyltransferase activity more than fibers from wheat or carrot.³⁴ This result suggests that colonic bacteria may play an important role in modulating glucuronidation, and that diet-derived substrates for colonic bacteria can influence detoxification. (Clinically, the important application of this concept is to focus on gastrointestinal restoration and recolonization of the colon with symbiotic bacteria and prebiotics, while also providing a nutritional support program for hepatic detoxification phase I and phase II balance.)

Silymarin and glucuronidation. Milk thistle concentrate containing silymarin is another botanical medicine that influences cytochrome P450 and UDP glucuronosyltransferase activity. In a human cell culture study, researchers reported that silymarin significantly reduced cytochrome P450-3A4 enzyme activities, as well as those of glucuronosyltransferase 1A6 and 1A9.³⁵ This result may have potential clinical importance because these are hepatic drug-metabolizing enzyme systems that are important for first-pass detoxification of a variety of pharmaceuticals. Although this was a cell culture study, it does call into question the potential effects of milk thistle concentrate, when administered with specific pharmaceuticals, on their detoxification.

One can learn from this study to be aware that specific substances in botanical medicines may have influence on specific aspects of either phase I or phase II detoxification systems and alter the metabolism of certain medications. One should always ask patients what nutritional supplements and botanical medicines they are currently taking and assess the potential interaction of these various substances with their detoxification processes before administering other therapeutic agents.

Biochemical Individuality and Toxic Response

Modifying Susceptibility to Environmental Toxicants: Diet, Lifestyle, Environment

Although genetic predisposition may confer certain absolute risks in the response of an individual to toxic agents, most aspects of detoxification and resistance involve highly modifiable nutritional, environmental, and lifestyle factors. The cytochrome P450 enzymes are located primarily in the liver. However, several other organs, including the small intestine, lungs, brain and kidneys, contribute in a lesser way to the P450-mediated oxidation of both xenobiotics and endobiotics such as hormones and neurotransmitters. There are numerous factors that influence phenotypic expression of these critical enzymes. Although there have been over 30 different P450s characterized in detail in humans, it appears that the majority of P450 activity is carried out by about six different isoforms.³⁶ The impact of various physical, chemical, and microbiological agents upon P450 activity is highly complex and may involve upregulation, downregulation, inhibition, or stimulation of enzyme activity.

Fasting. One significant consideration for the natural medicine clinician is the impact of fasting upon detoxifying enzyme function. For the most part, P450 enzymes are relatively resistant to depletion during fasting, and may even be significantly induced by products of starvation such as ketones and xenobiotics released from stored fat. On the other hand, the conjugating enzymes are highly dependent upon dietary provision of adequate amounts of substrate and are consumed rapidly under states of high xenobiotic load or oxidative stress.³⁷ Complete fasting, juice fasts, or other nutritionally marginal fasting regimens may exacerbate systemic toxicity,³⁸ particularly if the fluid intake is low and there is reduced fecal elimination. This may result

in a marked rise in highly toxic bioactive intermediates and free radicals, with a concomitant decrease in phase II detoxification activity, because those regimens don't provide adequate substrate for phase II detoxification. For example, sulfation is particularly susceptible to inhibition due to compromised cofactor status, and the serum sulfate level is decreased in individuals who are fasting. Humans excrete approximately 20 to 25 millimoles of sulfate in 24 hours; therefore, sulfate reserves must be maintained through dietary intake of sulfur-containing amino acids or inorganic sulfate, both of which have been shown to support increased serum sulfate levels.³⁹

As discussed in Chapter 22, imbalanced detoxification can result in marked oxidative stress and may be particularly deleterious to chronically ill patients whose antioxidant reserves are already exhausted or significantly weakened. Perhaps in the past, when tissue burdens of xenobiotics and heavy metals were low, complete fasting regimens were of significant benefit. However, the modern human is probably ill advised to follow such traditional detoxification methods for lengthy periods of time.

Amino acid needs in phase II detoxification.

Phase II detoxification systems are particularly dependent upon and responsive to adequacy of substrates to carry out the conjugation of oxidized intermediates. Adequate amounts of protein, with special attention to glycine, L-glutamine, methionine, L-cysteine, and N-acetylcysteine, along with inorganic sulfate, selenium and additional taurine, are all very important in the support of phase II activity.^{40,41,42,43} Lipic acid supplementation markedly enhances the level of intracellular glutathione in states of adequate sulfur amino acid intake.⁴⁴ Undenatured whey protein, rich in glutathione precursors, has been shown in several studies to increase cellular and plasma glutathione.⁴⁵ Cruciferous vegetables significantly upregulate phase II enzyme activity.⁴⁶ Antioxidants also provide a highly supportive role in liver detoxification by reducing oxidative stress resulting from phase I activity and by preventing glutathione consumption by reactive oxygen species. Milk thistle, curcumin, and green tea extracts are particularly useful antioxidants for the liver;^{47,48,49} silymarin (milk thistle) is mediated through the upregulation of phase II enzymes such as glutathione-S-transferase.

Other dietary factors. Other nutritional factors impact detoxification. High carbohydrate diets bring

about downregulation of P450s in a pattern that results in an undesirable reduction in the metabolism of several drugs and hormones. Intestinal dysbiosis may inhibit specific P450 activity through altered enzyme activity. On the other hand, supplementation with probiotic bacteria can markedly reduce the adverse effects of bacterial endotoxin upon the liver, as well as decreasing gut permeability.⁵⁰ Inhibition of nitric oxide synthesis may improve detoxification in inflammatory liver conditions.⁵¹ Certain types of dietary fiber markedly enhance the activity of both phase I and phase II detoxification systems in the liver.⁵² Fiber also decreases stool transit time, acts to sequester conjugated xenobiotics and endobiotics located in the bile, and reduces the level of bacterial deconjugating enzymes in the stool. All of these effects reduce the recycling of xenobiotics and endobiotics through the enterohepatic circulation.^{53,54}

Exercise. Exercise, if accompanied by adequate calories and protein, has been shown to result in liver hypertrophy and a multifunctional induction of detoxification enzyme systems, as well as a marked increase in antioxidant enzymes and reduced glutathione in several organs.^{55,56,57} Additionally, exercise results in a mobilization of extracellular fluid and lymph where xenobiotics often temporarily reside after being released from cells by exocytosis or other mechanisms. Sweating augments the liver's detoxification mechanisms as it is an important route of elimination for both organic^{58,59} and metallic^{60,61} toxicants.

Nutritional and Environmental Regulation of Toxic Metals

Nutritional adequacy has a marked influence upon the absorption, retention, toxicity, and excretion of toxic metals. For example, the effect of lead on cognitive and behavioral development is increased with iron deficiency, which also leads to increased gastrointestinal absorption of cadmium. Cadmium competes with zinc for binding sites on metallothionein.⁶² Iron deficiency also increases the uptake of aluminum.⁶³ The absorption of several other toxic metals may be enhanced by increased intestinal permeability. Inadequacy of certain minerals can lead to enhanced retention of toxic metals. Through increased absorption, calcium deficiency increases both lead and cadmium body burden, and selenium deficiency increases mercury retention.

Toxic metals compete with nutritional minerals, leading to displacement of nutrient minerals from protein binding sites, as well as excessive loss of minerals from the body.⁶⁴ Because of this, the requirement for several nutrient minerals may rise significantly above the RDA in the metal-toxic patient. The clinician must also be aware that certain nutritionally necessary metals (e.g., iron, copper) can become conditionally toxic, and perhaps should only be supplemented if a deficiency is determined. The best example of this is excessive iron stores in patients who are homozygous or heterozygous for a hemochromatosis mutation, the most common genetic disorder. Although homozygotes are relatively uncommon, heterozygotes for this disorder may be as high as one in five in certain populations, and these individuals may be at risk for manifestations of iron toxicity, particularly if iron supplementation is administered.⁶⁵ Other nutrient metals (e.g., manganese) may be nontoxic unless control of absorption is bypassed through inhalation or injection.⁶⁶

The excretion of toxic metals is governed by a complex chain of interwoven activities. If any link in this chain is broken, proper elimination of the toxic metal may not take place. Toxic metals must be released from the cell, moved from the extracellular fluid into the blood, transported from the blood to the liver or kidneys, and then transported from the kidneys to the urine or from the liver into the bile. Once the metal is in the bile, it must then be transported out of the body in the stool before it can be reabsorbed back into the circulation.

For example, the first step in mercury excretion involves binding of the mercury to metallothionein (MT) or glutathione within the cell. Metallothionein production, in turn, is highly inducible through exercise and nutritional adequacy of zinc (zinc deficiency results in MT depletion). Metallothionein production is also induced by supplementary L-cysteine or by brief periods of oxidative stress (as with aerobic exercise).⁶⁷ MT works in cooperation with glutathione in the initial mobilization of mercury from cells and it also shares intracellular antioxidant activity with glutathione.⁶⁸ Selenium may also play a role in binding to mercury within the cell and forming a transportable complex. Therefore, selenium supplementation has been recommended in the treatment of mercury toxicity.⁶⁹

Once mercury is mobilized by MT or glutathione, it is transported through the cell membrane (probably by exocytosis). Mercury must then be carried away from the cell to limit toxicity upon the cell membrane and to transport mercury to the liver. Exercise is probably helpful in accelerating the movement of mercury from the extracellular fluid through the lymph and into the blood. Hyperthermic therapy (e.g., sauna) may be helpful in mobilizing mercury directly from the extracellular fluid.⁷⁰ Once the mercury reaches the liver, it usually undergoes conjugation with glutathione and is transformed into a mercapturate. The mercury mercapturate is then released into bile.⁷¹

Both the liver and the kidneys are highly sensitive to glutathione depletion by mercury. Hepatic and renal glutathione production can be enhanced by supplementing the diet with L-cysteine, N-acetylcysteine, glutathione, cruciferous vegetables, dietary fiber, undenatured whey protein, lipoic acid, onions, and garlic. Lipoic acid may also assist in this process by directly binding inorganic mercury in the liver and accelerating its excretion into the bile, while simultaneously inducing the formation of glutathione.⁷²

Once mercury has entered the intestine through the release of bile, it must leave the body via the stool. Optimal gastrointestinal function is very important to prevent recycling of mercury through the enterohepatic circulation. Fiber has been shown to have a significant effect in lowering total body burden of mercury through sequestration of intestinal mercury and reduction in stool transit time.⁷³ Other factors, including increased gut permeability and intestinal dysbiosis resulting in deconjugating bacterial enzymes, help determine how efficiently mercury can leave the body once it has passed from the liver into the small intestine. Since 90% of excreted mercury leaves the body through the enteric route, colonic elimination is a vital component in maintaining an unbroken and efficient chain of excretion from the cell to the outside of the body for mercury as well as a host of other toxicants.

Assessing the Toxicologically Impaired Patient

Patient History

A carefully gathered toxic exposure history is a vital part of the clinical evaluation. The mnemonic **C(H2)OP(D4)** will aid in remembering important elements of the toxic exposure history.

Community	City and neighborhood air quality, noise, electromagnetic fields
Home	Home heating and ventilation, cleaning chemicals, pesticides, paints, carpets, building materials, molds, allergens, water
Hobbies	Toxic chemicals, paints, solvents, metal fumes
Occupation	Workplace air quality, toxic chemicals
Personal habits ..	Smoking, drinking, drug use, sun exposure, exercise, stress management
Diet	Overall quality of diet, over- or undereating, meat eater or vegetarian, fast foods, snack foods, deep fried foods, fish and seafood, organic or non-organic foods, food allergies or intolerances, leaky gut syndrome, abnormal microbial ecology of the digestive tract
Drugs	Prescription and nonprescription
Dental	Amalgams placed and removed, extractions, root canals
Development	Mother's pregnancy history (e.g., smoking, drugs, drinking, toxic exposures, dental work), childhood exposures (e.g., leaded paints, pesticides, secondhand smoke)

Patients may not be aware of important sources of toxic exposure. They may also have genetic, nutritional, or lifestyle factors that place them at elevated risk for toxicologically-mediated health problems.

Laboratory Assessment

The field of toxicogenomics is in its infancy, but several labs have begun to offer toxicogenomic assays to help in evaluating a patient's genetic risk of toxin-mediated illness. Evaluations of SNPs to assess cytochrome P450 variability, DNA or RNA amplification techniques (primarily polymerase chain reaction—PCR) to assess adequacy of metallothionein or glutathione S-transferase activity are examples of toxicogenomic tests that are (or are becoming) commercially available to the clinician.

Some laboratories have developed panels that include evaluation of several factors relative to a particular toxicologic system. For example, an available metallothionein profile measures serum zinc, serum copper, serum ceruloplasmin, serum ceruloplasmin copper, non-ceruloplasmin (“free”) copper, whole blood reduced glutathione, whole blood metallothioneins, copper/zinc ratio, reduced glutathione/metallothionein ratio, zinc/metallothionein ratio. Other examples include the functional liver detoxification profiles offered through several commercial laboratories. In these tests, patients are given drugs (often acetaminophen, aspirin, and caffeine) as a single oral dose. Urine is gathered following the ingestion of the test substance, and levels of metabolites processed through phase I and phase II detoxification are measured. Although no profile currently exists which assays the function of more than a few out of the several dozen possible detoxification enzymes, these tests often do provide useful information for the clinician.

Organic toxicants. In some cases, an occupational history will provide clues about specific toxicants to be searched for. Some toxicology laboratories offer extensive panels to quantify the level of organic toxins in blood, urine, or adipose tissue. Available panels include such things as PCBs, organochlorine pesticides, PBDE fire retardants, furans, and dioxins. Body burdens for these agents are accurately assessed by providing a small sample of adipose tissue (often taken through a small incision under the umbilicus). For example, an electric utility worker with chronic fatigue syndrome was shown to have a high body burden of PCBs, as measured in a provided fat biopsy. In this case, PCB tissue levels can be monitored in a serial fashion following detoxification efforts. Such assessment may also help a patient to support a disability or worker's compensation claim.

However, unless a specific chemical or family of chemicals can be suggested by an exposure history, the range of possible organic toxicants is far too vast to be determined practically and financially in most cases. It is generally more realistic to assume that all functionally impaired patients carry a wide range of synergistically active organic toxicants at various levels, and focus instead upon engaging the patient in a comprehensive detoxification program using outcome-based measures and functional testing to gauge success.

Metal toxicants. On the other hand, the definitive assessment of a patient's heavy metal burden is relatively simple and probably should be performed early in the assessment of most patients with poly-symptomatic, chronic illness. Metal-toxic patients present a unique clinical challenge and, if a significant toxic metal burden is present, the outcome of clinical intervention may be disappointing unless the metal burden is effectively diminished. Once metal burdens are diminished, patients often respond far more effectively to other clinical interventions.

There is a limited number of toxic metals commonly found in the human and most labs provide panels that include most of these metals. Hair analysis is a simple and inexpensive screening test for levels of a few metals such as lead or methylmercury (from seafood). However, there are confounding factors that can make it difficult to use for individual patient diagnosis—for example, some anecdotal reports indicate that low levels of hair mercury in autistic children may indicate poor excretion rather than normality, whereas high levels of hair mercury may indicate normal mercury excretion patterns. Furthermore, the precision of this methodology in determining long-standing body burdens of most other metals is probably too low to base confident clinical decisions upon, and some toxicology authorities suggest that hair analysis be limited to population screening.⁷⁴

Conventional toxicologists generally rely upon other methodologies of assessing metal burden to gauge clinical decision making. “Acceptable” blood levels of lead in children and adults, as well as blood and urine levels of several other metals in industrial settings, have been widely suggested in published literature. However, the limitation of blood or urine tests is that they largely reflect only the level of ongoing exposure to the metal and may bear little relationship to tissue levels. Since tissue biopsy for heavy metal levels is impractical, post-provocative urine testing is probably the most reliable

means to assess body burden of metals acquired through long-standing, low-level exposure, especially in the assessment of low-level inorganic mercurialism.⁷⁵

The Detoxification Lifestyle

When working with chronically ill patients whose health is impacted by toxicological stresses, clinicians need to provide education to help these individuals develop habits of living that will reduce their exposure to toxicological factors and improve the efficiency of their detoxification mechanisms. The mnemonic **A NERD** will help the clinician to remember the important elements of a detoxification lifestyle. Patients who learn to follow these habits of living are creating a foundation for better long-term health, and their response to more extensive clinical interventions will be more successful.

Avoid exposure to all known sources of toxicity. Chemical dependencies, smoking, excessive alcohol, unnecessary prescription drugs, toxic work environments, homes with leaded paint, severe air pollution, polluted drinking water, and standard North American diets—particularly sugary drinks, junk foods, processed meats, fast foods, and deep fried foods—should be avoided. For some patients, removal of dental amalgam fillings might be indicated.

Nutrition must be optimized for efficient detoxification. The diet must be based upon whole foods (plenty of vegetables, fruits, and fiber) and should emphasize foods with a net alkalinizing impact with lower amounts of acid-forming foods. Generous portions of cruciferous vegetables should be eaten daily, along with modest amounts of olive oil, as well as onions, garlic, and modest amounts of lean, unprocessed protein. Supplements can include alkalinizing minerals (Ca, Mg, K, Zn), along with multivitamin/trace elements, essential fatty acids (DHA/EPA), N-acetylcysteine, lipoic acid, and antioxidant support (vitamins C and E, grape seed extract, green tea extract). Undenatured whey protein supports synthesis of glutathione. Detoxification medical food products are available with a base of undenatured whey, rice, or pea protein, along with a range of nutrients to support detoxification. These can be used as a supplement to, or in replacement of, one meal per day to simplify the daily detoxification supplement program.

Exercise accelerates lymphatic flow, induces sweating, and increases metabolism and detoxification effi-

ciency. Exercise should be a daily part of the detoxification lifestyle.

Rest, including proper sleep, relaxation, and stress management, is an essential element in the detoxification lifestyle.

Detoxification as a specific therapeutic activity should be considered as a periodic means to improve vitality and reduce toxic body burdens. Traditions of fasting and purification have been incorporated into the way of life and healthcare systems of most traditional cultures, and variations on fasting are central to the practices of natural, integrative, and functional medicine. Taking a few days to rest and rejuvenate the gastrointestinal tract and bolster the excretion of xenobiotics is a lifestyle habit that can improve a patient's vitality.

Nutritionally-Controlled Detoxification

Rigden has described the “enterohepatic resuscitation program for chronic fatigue syndrome” and reported significant improvement in the majority of patients studied.⁷⁶ In this uncontrolled study, subjects consumed a limited, low-calorie diet supplemented by a medical food product designed to provide nutritional support of hepatic detoxification phase I (antioxidants) and phase II (conjugation substrates).

Bland, in another uncontrolled study, utilized a similar program with a high degree of success in 106 patients with a variety of chronic illnesses.⁷⁷ Using a much different approach, clinicians prescribing exercise and saunas combined with supplementary niacin, calcium, magnesium, and polyunsaturated oil report a significant reduction in tissue PCBs and other fat-soluble xenobiotics in toxic patients.^{78,79,80} Europeans have successfully utilized sauna treatment to decrease mercury levels in exposed workers.⁸¹ None of these approaches have been validated with controlled clinical trials.

Many clinicians have successfully prescribed a nutritionally-controlled detoxification program that follows this general approach:

- Mild to moderate caloric restriction to promote fat loss
- No fast foods, junk foods, deep fried foods
- High quantities of fresh vegetables and often fresh vegetable juice
- Very simple, low processed, oligoantigenic (low allergy potential) foods—protein from chicken, fish, and legumes, and whole grains such as brown rice, millet, and quinoa
- Medical food product designed to support detoxification (1–3 times per day, depending upon quantities of other foods eaten)
- Light exercise daily
- Sauna 3–5 times per week

This program is continued for 5 to 21 days or more, depending upon the patient's condition and the clinician's experience.

Gastrointestinal Rehabilitation

Gastrointestinal rehabilitation is a concept familiar to practitioners of functional medicine. Many clinicians consider gastrointestinal rehabilitation an essential part of any detoxification program, and will often institute such a program before beginning any detoxification interventions. In this text, we refer to the process of GI rehabilitation as the 4R Program (Remove, Replace, Reinoculate, and Repair), and it is described fully in Chapter 28. An effective GI rehab program will reduce intestinal permeability, improve nutrient absorption, and increase immune response to gut pathogens while diminishing hypersensitivities.

Summary

The study of detoxification mechanisms, processes, and influences is a young field. The growing body of research is helping clinicians understand their patients better, particularly in three main areas:

- the role of genetic individuality in detoxification,
- influences of diet, nutrition, environment, and lifestyle on detoxification, and
- the importance of staying current with emerging data on food/drug and herb/drug interactions that affect detoxification.

Even without a mature evidence base, knowledge of basic mechanisms and processes can guide clinicians in assessing and improving detoxification and biotransformation in their patients. Specific nutrients play key roles in supporting both phase I and phase II detoxification, and a number of clinical approaches are available to those with the proper knowledge and training.

Detoxification Procedures—A Disclaimer

The following two subsections of this chapter will provide the reader a glimpse into clinical approaches

that may help patients decrease their toxic burdens. We have presented in Chapters 13, 22, and elsewhere in this chapter a portion of the large and growing evidence base about the presence and persistence of exogenous toxic substances in humans, their effects upon our physiology and biochemistry, and some interventions that may help to strengthen and balance the body's own detoxification systems. Unfortunately, there is a dearth of evidence about how to actually detoxify patients whose illnesses are caused by, or exacerbated by, a toxic burden. As Dr. Crinnion explains below, even the differential diagnosis is difficult.

Healthcare practitioners are often faced with the challenge of when to act and what to do in the absence of compelling evidence. Historical uses and clinical experience do form a portion of the evidence that informs all clinical decisions. It seemed to us that, in the face of the significant and well-documented body burden of toxins we all carry, providing practitioners with some clinically-derived views on clinical detoxification procedures is important. We have, therefore, invited Dr. Walter Crinnion and Dr. Peter Bennett to share with you the approaches they have used with their patients for many years. It is our hope that by increasing awareness of such practices, we may help to stimulate interest in research on these and other approaches that may be of benefit to patients. That research is badly needed.

— The Editors

Systemic In-office Detoxification

Walter J. Crinnion, ND

Introduction

"Is this patient toxic?" The answer to this question is "Yes." Virtually all patients today have a body burden of toxins. According to one recent study, the average number of toxins found per person was 91.⁸² The CDC has also picked up the challenging question of how many toxins are in us. They have already published two reports and will continue to publish their research.⁸³

Instead of asking *whether* the client is toxic, the more clinically relevant questions are:

- Is this patient's toxic burden a causative factor in his or her illness?
- If so, is it an obstacle to cure?
- If yes, what can be done to help the patient?

Unfortunately, the answers to these questions can be hard to come by. The subject has not been adequately researched in even small clinical trials (see sidebar). Connecting the toxic burden directly to the patient's illness is very difficult and sometimes impossible. However, as a clinician who has worked in this field for more than 20 years, I strongly believe that many patients with chronic illness will benefit from the procedures I am about to describe. Where there is evidence to share, I will cite it. As always, each individual practitioner must decide what to recommend for his or her patients.

Absence of Good Research on Toxicity and Illness

Although the evidence base describing many mechanisms of toxic insult is well developed for a host of different environmental toxins and pharmaceuticals, there is a notable lack of evidence to help clinicians differentiate the clinical presentation of symptoms that may involve a toxic exposure from those that do not. Most of our clinical knowledge of toxic effects has been derived from acute exposures in amounts far in excess of what is likely to be found in the everyday environment of most patients (or from animal studies, which do not extrapolate fully to human patients). Researchers have not yet clearly described and quantified, in ways that lead to good differential diagnosis, detectable long-term clinical effects of low-level exposures to multiple toxic sources (many of which may be working through common pathways). So, the clinician's challenge is very difficult. Common complaints such as vomiting, diarrhea, nausea, and abdominal pain may stem from a vast array of causes; endocrine disruption and neurological symptoms likewise have multiple etiologies. Many

of the subtle effects that we might expect to see in patients, based on bench science and animal research, would (for now) only be detected in large population-based studies over long periods of time; and those studies have, for the most part, not been performed. Factors that further complicate clinical assessment are the age of the patient and the role of individual susceptibility. Infants and young children have different (and often fewer) defenses than adults; elderly people may be more vulnerable to certain toxic agents than younger adults. And individual variability in response to toxic agents, both for environmental toxins and for pharmaceuticals, can be great—never has it been more true that "one man's meat is another man's poison." An excellent summary of what we still need to learn about endocrine disrupters (just one example of environmental toxins) can be found in a 2003 article by Daston et al.⁸⁴ The April 2004 issue of *Pediatrics* had a special focus on toxicity problems in infants and children; two reviews of GI toxins⁸⁵ and pesticides⁸⁶ are particularly recommended.

Assessing and Treating Toxic Burden

Determining whether the toxic burden of your patients must be dealt with in order for them to get better requires, in part, an understanding of what organs and systems are affected by the common toxins. In-depth discussion of those topics can be found in the earlier parts of this chapter and in Chapter 22. It also requires recognizing the common signs and symptoms of toxin buildup—a more difficult task, as described above. Recognition of these signposts greatly assists the clinician in designing the most efficacious treatment program. In addition to recognizing the telltale signs of toxicities in a good history and physical exam, clinicians should also be aware of laboratory markers that reflect toxin load, as these assessments can help to clarify the patient's condition. A limited number of tests are useful in establishing that patients could benefit from lowering their toxic burden. Measurements of chlorinated compounds and solvents can be done from both serum and adipose samples. Urinary measurements can be taken for heavy metals, organophosphate pesticide metabolites, and phthalates. Fecal measurement of toxic metals is also available and can be used for testing pediatric clients.

Finding the Source of Exposure

The documentation of xenobiotic presence in an individual's serum, adipose tissue, stool or urine can be important in formulating an effective therapeutic protocol. This initial testing provides a basis on which to initiate treatment, a baseline to refer back to in order to help judge your progress, clear motivation for the client to follow your recommendations (depending upon how well the practitioner presents this information), and an indication as to the possible sources of toxin exposure. The importance of finding the source of toxin exposure in an individual cannot be overemphasized. For many persons, the identification and elimination of the source comprises the majority of necessary treatment. Other individuals will need more help to reduce the total toxic burden.

Finding the source of exposure typically includes taking a detailed environmental history (past and present) of the person, checking out towns she or he has resided in, and possibly doing some home air-quality testing. Finding exposure sources in various towns can be accomplished with the help of two websites: www.scorecard.org (just enter the zip code for a listing of local polluters and pollutants) and www.atsdr.cdc.gov/hazdat.html.

If the exposure is ongoing, it is imperative that the source be removed before beginning a detoxification program. Once the exposure has been identified and dealt with, the depuration program can be safely started. The program should be based on the type(s) of xenobiotics that appear to be the causative agents in the client's illness. Heavy metals will often be dealt with differently from lipophilic xenobiotics, as they can be easily and directly chelated, while the lipophilic chemicals cannot.

Heavy Metal Chelation

Measuring heavy metals in clients for whom toxicity is suspected as a factor in their illness is a useful step. When these compounds are found, a protocol can be initiated to mobilize the heavy metals, utilizing dimercaptosuccinic acid (DMSA). This compound is FDA approved, and is well researched for safety and efficacy in clearing mercury, lead, and other heavy metals from animals and humans.^{87,88,89} DMSA is available from pharmacies under the names Chemet and Succimer, as well as from other sources.

DMSA is given in a body-weight dose of 30 mg/kg, and has been shown to be safe in that dose for children (including infants) who have been poisoned with both mercury and lead.^{90,91} Using the published body-weight dose of DMSA, the two protocols that seem to be most commonly used are three days of DMSA followed by 11 days without, or five days of DMSA followed by nine days without. A repeat urinalysis at the beginning of every fifth round (at week 10, 20, 30, etc.) can be used to monitor the client's progress. Over the years, we found that most of our clients did 20 or 25 rounds before stopping. On the days they were not taking DMSA, they were supplemented with low levels of zinc, copper, molybdenum, and manganese to replete any possible micromineral loss from the DMSA.⁹² Fairly high levels of magnesium were required, often accompanied by magnesium sulfate shots, to avoid magnesium depletion. While magnesium does not appear on the affinity list for DMSA, it appears to be mobilized from the body in this process.

Lipophilic Xenobiotics

While the clearance of heavy metals through chelation is fairly straightforward, the mobilization of lipophilic compounds is not. The body burden studies previously mentioned, along with numerous smaller

studies worldwide, have alerted us to the presence of chlorinated pesticides and PCBs in everyone tested. The majority of the compounds found in everyone tested are lipophilic rather than water-soluble. Lipophilic substances have no efficient means of exit from the body, as the bowels are designed to retain fat-soluble substances. In order to help these compounds leave the body, saunas have been employed with documented success.^{93,94,95,96} Sauna therapy allows the xenobiotics stored in the subcutaneous fat pads to be released through the skin, while those in deeper fat stores are released into the circulation. The compounds in the subcutaneous fat pads include both substances absorbed through the skin⁹⁷ and some compounds from the circulation (including medications). Numerous compounds have been documented to exit the body via the skin, including necessary minerals,^{98,99} zinc, copper, iron and manganese; the heavy metals lead,^{100,101} cadmium,¹⁰² and mercury,¹⁰³ plus various medications.

Compounds that are moved out through the skin are often grossly detectable by smell and by their damaging effect on articles of clothing. Clinical experience with numerous patients undergoing thermal chamber depuration has provided many indisputable olfactory encounters with chemical compounds being released in the sweat. Two patients undergoing thermal chamber depuration experienced disintegration of clothing that was worn in the chambers. There are two published accounts of thermal chamber depuration being successfully used in the treatment of chemically sensitive persons,^{104,105} including the reduction of serum hydrocarbon levels.

The fat-soluble compounds released into the circulation through sauna therapy do not exit the body easily. These compounds must again be processed by the same phase I and II detoxification pathways that were unable to successfully transform and excrete them before. Therefore, it is important to attempt to increase the excretion of fat-soluble items from the bowels when sauna depuration is used. Increased use of dietary fiber and chlorophyll,¹⁰⁶ and use of dietary substances that interrupt the enterohepatic circulation¹⁰⁷ may be useful. When proper nutrition and other physical therapy modalities are included with thermal chambers, good clinical results, such as those with chemically sensitive persons,^{108,109} can be achieved.

Summary

Utilizing these approaches (chelation for heavy metals, sauna and enhanced fecal excretion for lipophilic toxins), the author has noted significant improvements in numerous chronic illness states. By reducing the body burden on the client (through avoidance of the source, chelation, and mobilization of lipophilic substances), the self-healing functions of the body can work unfettered.

Home-based Detoxification

Peter Bennett, ND

Introduction

Historically, detoxification therapies have been applied in clinical settings, in medical spas, and at home. Although early practitioners of this approach did not call it “detoxification therapy,” their methods of hydrotherapy, fasting, regulated diet, and Nature Cure are similar to many modern detoxification methods.¹¹⁰ By studying the work of Sebastian Kneipp,¹¹¹ John Harvey Kellogg,¹¹² O. G. Carroll, and John Bastyr,¹¹³ one gets the impression that doctors and healers found that the best results happened in a setting where the patient could be closely watched. Just preceding this part of the current chapter, a doctor-supervised program was described. Unfortunately, time and cost prohibit this for many patients today, so a home-based program may be recommended to patients, within certain guidelines.

A complete detoxification program should focus on three targets:

1. Retrieve gut functioning (4R program—see Chapter 28);
2. Reduce heavy metals; and
3. Reduce organic chemicals stored in fat tissue.

A one-week home-based program may help patients detoxify key dysregulating influences that are obstacles to regaining stability and balance in their health. On a biochemical level, such a program can help to support cellular functioning, improve the filtration capacity of the liver, stimulate the excretion of toxins through the kidneys, bowel, and skin, support gut repair, and improve neuroendocrine balance in the hypothalamic-pituitary system.

Such claims may seem exaggerated in a world that relies heavily on expensive and high-risk interventions for patient complaints, and—unfortunately—these natural approaches to detoxification have rarely been researched. However, even a brief review of the literature detailing the powerful negative health effects of toxicity (see Chapters 13 and 22 and the first parts of the current chapter) demonstrates that it may be important to help certain patients relieve some of the body burden that modern living imposes.^{114,115}

The home detoxification program described here has been used by thousands of patients with reportedly excellent results. It is fairly easy and effective but the clinician needs to be prepared to teach patients what to do, and to offer the appropriate cautions. Patient instructions must be provided and reviewed carefully, and the practitioner must be available to answer questions after patients have started the program. A patient handout such as the one shown in Figure 31.2 can be used to guide your patients.

Elements of the Detoxification Program

The essential steps of this home-based program are:

- Brief water fasting (two days),
- Oligoantigenic diet (five days) and slow reintroduction of omitted foods,
- Saunas and hydrotherapy (one month), and
- Nutritional supplements (one month).

In the author's experience, using all these elements together gives reliable results.

Fasting

Fasting on water for a short period can be a safe and powerful way to rejuvenate the mind and body. While water fasting may not be suitable for severely compromised patients (see recommendations earlier in this chapter), research has shown that calorie restriction and fasting help to alleviate hypertension,^{116,117} diabetes,¹¹⁸ epilepsy,^{119,120} and rheumatoid arthritis.¹²¹ Recent research has shown that calorie restriction may be the most powerful way known yet to extend lifespan.^{122,123} Studies have shown that high glucose and insulin damage mitochondria, and calorie restriction (fasting) reduces the total amount of oxidative stress within the cellular mitochondria.^{124,125}

Fasting may improve liver function. Fasting has traditionally been thought to enhance the liver's ability to clear out metabolic byproducts from the blood stream, and regenerate the liver's ability to function in a healthy way. There are indications from a few animal studies that dietary restriction may help to reduce the risk of age-related diseases associated with impaired lipid metabolism.^{126,127} However, caution is indicated because long-term fasting or fasting in a polluted environment can deprive the body of nutrients that are critical to a patient's health. Fasting should be done for short periods of time in a pure environment and, in my practice, I recommend taking vitamin C during fasting in the range of one to four grams per day.

Fasting may benefit cognitive functioning. Several studies have shown that as severe liver toxicity progresses, the patient fails to break down valium-like compounds that create a toxic state.^{128,129} One might hypothesize a continuum of such effects for patients who are not nearly so ill. Patients who fast often report a sense of renewal and clearer thinking. Fasting allows the liver to reduce the presence of recycled chemical messengers like adrenalin and other stress hormones, which often have a second chance to restimulate the nervous system when they are not biotransformed and excreted appropriately.

Caloric restriction improves immune function. Caloric restriction, which can be achieved by short-term fasting, appears to have measurable benefit for the immune system.^{130,131} It rests the intestines and liver, both key sites of immune function. It is estimated that 60% of our immune system resides in our intestines. By resting this major site of immune function with fasting, the patient's immune function may be potentiated. A fast of 36 or 60 hours significantly increases the power of white blood cells to destroy pathogenic bacteria.¹³² Conversely, eating can depress immune function and have a proinflammatory effect,^{133,134} whereas energy restriction may restore the impaired immune response.¹³⁵ Studies have shown that a glucose challenge increases the generation of reactive oxygen species (ROS), while nutritional restriction can inhibit ROS generation by leucocytes.^{136,137}

Seven Day Detoxification Plan

Please follow precisely all the instructions in this one-week home-based detoxification plan. It has been used with thousands of patients, many experiencing excellent results. This program of rest and renewal for your body can reduce aches and pains and symptoms of chronic disease; it can help you feel healthier and more energetic.

How Does It Work?

The body has its own self-healing mechanisms. This seven-day program strengthens your body's healing forces in a short period of time. By stimulating your natural capacity to release and excrete toxins, you can remove some of the obstacles that are keeping you from being completely healthy. Detoxification is like an oil change for your car. It cleans and improves the filtering of your internal fluids in a way that prevents your body's engine from breaking down, and produces immediate benefits in fighting existing disease. It is a simple program using a special diet, supplements, heat, and contrast hydrotherapy.

Detoxification Program Summary

- Two day water fast with bed rest if necessary
- Five days of rice, fruit and vegetables
- Protein shakes 1-2x/day daily during days 3 to 7
- Supplements as recommended
- Shower hydrotherapy treatment at least once per day
- Daily saunas. Don't do the sauna on the fasting days
- Sleep at least 6-7 hours a night
- Avoid "enervation" at night (TV, theater, movies, parties)

Diet

The program begins with a two-day water fast followed by five days of rice, fruit, and vegetables. (Additional details on the fast and the diet are shown below.) While on this diet, you should supplement these foods twice a day with a whey or rice protein-based powder. Add 2 rounded scoops in juice, blended, 2-3 times a day for breakfast and snacks to improve protein status during detoxification.

Days 1 and 2

Consume water, lemon water, and herbal tea only. Be sure to drink a minimum of 8 glasses of these fluids per day. This fluid fast is extremely helpful in achieving optimal detoxification. Some people cannot tolerate this two-day fast, can't afford to lose any weight, or are in a debilitated condition. These people should add the rice or whey protein and fruit juice 2 to 3 times per day to the other fluids.

Days 3 to 7

Following the water fast, a typical day's menu should reflect the general choices shown below. (You may need to eat more or less depending on your appetite.)

Reintroduction of Omitted Foods

Following your seven-day program, you should reintroduce foods back into your diet slowly - one food at a time, every 1 to 2 days. This process may take up to a month. Focus first on protein sources from lean meat, fish, or eggs. Then add back beans and grains (other than wheat). Then introduce nuts. Finally, slowly reintroduce wheat, dairy, and soy. Each time a food is reintroduced, note any reactions - physical, mental, or emotional. Write them down and bring your notes to your next appointment.

Figure 31.2 Sample patient handout for home detoxification

Typical Menus

Upon arising 8 ounces of hot lemon water
Breakfast A protein shake made with fresh fruit and fruit juice; rice cakes; fresh fruit; herbal tea
Snack Fruit and/or a rice protein shake; herbal tea
Lunch Salad and soup, or rice and steamed vegetables, or yam and steamed vegetables (hot or cold)
Snack Fruit and/or rice protein shake; rice crackers; herbal tea
Dinner Rice and mixed vegetables (steamed or lightly sautéed), or soup and salad, or salad and baked sweet potato
Note Drink plenty of water and lemon water in these days as well.

Foods to Use and Avoid

Carbohydrates

Use: Brown rice, basmati rice, jasmine rice, wild rice, rice cakes/crackers, rice bread, rice pasta, and rice pancake mix (read labels to avoid any wheat content). If variety is required, you can use quinoa, millet, and amaranth grains.
Avoid: Sugar, honey, molasses, jams, artificial sweeteners, corn, wheat, spelt, kamut, barley and any products with these in them.

Legumes

Use: Mung beans, red lentils
Avoid: All other beans

Vegetables and Fruits

Use: All varieties of fresh produce can be used. They can be steamed, baked, lightly sautéed in a small amount of extra virgin olive oil, eaten raw, or juiced. Vegetables can be used in any combination and quantity desired. Fruits are to be eaten one variety at a time and away from other foods.

Fats and Oils

Use: Extra virgin olive oil and unheated flaxseed oil.
Avoid: All other oils including butter and margarine.

Beverages

Use: Non-caffeinated herbal teas, purified water (spring or filtered), lemon water (organic lemons only). (Squeeze 1/2 lemon into 1 litre of water and then drop the squeezed lemon peel into the water; at least 1 litre of this lemon water to be drunk per day.) Diluted fruit and vegetable juices (ideally, made fresh from a juicer).
Avoid: Coffee, black tea, all alcohol, soda pop and caffeinated/decaffeinated herbal teas/coffees.

Condiments

Use: Vegetable salt, sea salt, apple cider/balsamic/rice vinegars, Bragg's amino acids, wheat-free tamari, all spices
Avoid: Ketchup, mayonnaise, Worcestershire sauce, barbecue sauce, relishes, mustards, salad dressings and any packaged oil/liquid-based seasonings (i.e., chutneys; Indian, Thai, Chinese seasonings, etc.)

General Categories of Foods to Avoid

During your seven day detox program, all of the following foods put too much burden on the liver's detoxification ability and often disrupt digestion. They must be avoided.

- meat
- fish
- poultry
- eggs
- dairy products
- chocolate
- nuts
- beans (other than mung and listed soybean products)
- grains (other than rice, quinoa, amaranth, millet)
- preservatives and food coloring
- all packaged/processed/canned foods

Shower Hydrotherapy

This home therapy enhances circulation, detoxification, and metabolism. Ideally, it should be done every day. Take a hot shower for 3 minutes then switch to cold water for 30 seconds. Repeat the cycle 3 times, ending with the cold rinse. Make sure your entire body is showered this way. After you've finished three rounds, get out of the shower, dry off quickly, and go to bed or dress warmly till you refresh the body heat.

Sauna

Sauna therapy is extremely safe, and is a critical step in removing fat-stored toxins through the skin. As you sweat, many toxins that are stored in the fat and blood (PCBs, cadmium, lead, and industrial chemicals) are excreted through the skin. Do not sauna during the first two days of the program (the water fast).

Sauna Method

Use a low-temperature or infra red sauna, choosing a temperature from 150 to 170 degrees Fahrenheit. Drink 1 quart of warm water before entering and take water into the sauna with you, continuing to drink throughout the length of your sweat. Begin by staying in the sauna for fifteen minutes, then come out for a cold-water rinse.

Repeat this process for up to one hour. As you become more acclimated to the heat, you may increase your time a little each day until you reach two hours. The cold rinse is important because it stimulates circulation in the skin and removes waste material being excreted through it.

Dry Skin Brushing

The skin regulates body temperature, functions as an organ of elimination and has even been called the "third kidney." It averages 3,100 square inches of surface area, acting as a protective shield to the outside world. Dry skin brushing is an old natural healing method used to increase blood and lymphatic circulation. It removes dead skin cells, keeps the skin soft, improves blood and lymph circulation, and helps rid the body of toxins.

Skin Brushing Method

Brush your whole body once a day with a natural-bristle dry skin brush that you can find at health food stores. Start with your arms, front and back, moving from the fingertips up into the armpit, always brushing toward the heart. Then do each leg, front and back, starting at the feet and brushing upward. Follow each leg up through the pelvis, buttocks, abdomen, and lower back. Then do the chest and upper back, always brushing toward the heart.

If you wish, you can lightly do the face and head, using downward strokes. Keep the brush dry (never get it wet). Just as you wouldn't use someone else's toothbrush, be sure that only you use your skin brush. If skin brushing is painful, do it lightly and persevere-the discomfort will pass. The chest, abdomen, and inner thigh should be done gently and carefully.

Supplements

During this detox, the filtering mechanisms of the liver can become overloaded. Feelings of fatigue, headache, muscle pain, and nausea are common as toxins are mobilized and excreted. Taking certain supplements is a necessary step to support the liver, promote better detoxification, and prevent symptoms as much as

possible. Follow the supplements listed on your treatment program by your doctor. Supplements are prescribed according to your personal needs, but here are some general guidelines that will be followed:

1. The supplement program is for enhancing detoxification and improving circulation. It will be reviewed after 4 weeks.
2. The recommended supplements work by feeding the internal mechanisms of cells involved in detoxification. Work inside of the cells is driven by mini power plants called mitochondria (my-toe-con-dria). Toxins interfere with their energy production and this upsets the functioning of the entire cell.
3. The supplement program will not interfere with other supplements or medications that you are taking. All prescription medications are to be maintained unless directed by your physician.
4. You will not be asked to take any supplement that you do not absolutely need.

Fasting benefits arthritis. It has been demonstrated in research settings that fasting benefits arthritis.¹³⁸ The best results in treating autoimmune arthritis are achieved when a short fast is combined with a change to a vegetarian diet, and foods to which the patient is sensitive or allergic are removed.^{139,140} Fasting may be involved in changing the bacterial flora in a favorable way for patients with rheumatoid arthritis. Abnormal bacteria or microflora are present in the stool in patients with a variety of autoimmune problems such as Crohn's disease,¹⁴¹ rheumatoid arthritis,¹⁴² and ankylosing spondylitis.¹⁴³ Anaerobic bacterial species such as *Klebsiella* and *Proteus* have been implicated.¹⁴⁴ Fasting may play a role in changing bacterial flora, perhaps by enhancing competition and thereby giving dominance to probiotics. Changes in intestinal flora from a vegan diet have been documented.¹⁴⁵

Fasting contraindications. A two-day water fast is safe for most patients. Certain exclusions are important, such as diabetics, hypoglycemics, and severely nutritionally deficient individuals. The biggest risks to most patients are hypoglycemia and orthostatic hypotension with vertigo, sometimes resulting in fainting. Although these reactions are generally harmless, they can cause a fall. Patients should be warned to take extra care in standing up—i.e., getting out of bed or a hot bath, or getting up from a chair. If faintness or vertigo does not resolve within a very few minutes, patients should contact their practitioner.

There is medical literature to suggest that fasting for a prolonged period of time can diminish the body's stores of glutathione, making it more susceptible to aging and disease. Low tissue antioxidant status is found under dietary restriction because fasting lowers glutathione detoxification in the liver.^{146,147} People who are fasting should be very careful to avoid any chemical exposure, because lack of dietary protein makes the liver unable to process toxins optimally due to lack of adequate amino acid precursors that are important to the detoxification pathways. (As an aside, patients who are preparing to undergo surgery might have fewer complications from the anesthetic if they were put on a protein-dense regimen instead of clear fluids.^{148,149})

Oligoantigenic Diet

After a two-day water fast, a simple diet of rice, fruit and vegetables is then followed for five days. This is similar to an oligoantigenic diet, used for allergic, behav-

ioral, and digestive problems.¹⁵⁰ This simple diet provides enough caloric input to sustain the patient, but is very easy on the intestinal environment to allow optimum rest. The rationale for vegetarian fare is two-fold: vegetarian diets contain fewer potential food allergens that can cause activation of the gut-associated lymphoid tissue, and enhanced vegetable intake provides more soluble fiber, bioflavonoids, antioxidants, and complex carbohydrates. Some patients experience fatigue on this program; if it is not ameliorated with rice- or whey-based protein shakes, it will resolve upon resuming normal protein intake (unless, of course, the patient is allergic to the food being reintroduced). Chapters 28 and 35 provide detailed information on the use of oligoantigenic diets.

Sauna and Hydrotherapy

Sauna therapy (discussed earlier in this chapter) can support the removal of fat-soluble toxins from the body, and has been shown to provide relief of symptoms for patients with toxicity conditions.^{151,152} Sauna programs need to be carefully tailored to the individual patient and supervised closely, particularly with more compromised patients. Hydrotherapy has been employed for hundreds of years because of its ability to stimulate circulation. Although medical studies on the effectiveness of hydrotherapy for detoxification have not been done, there is a modest research base documenting its usefulness in symptomatic relief of many conditions, including rheumatoid arthritis,¹⁵³ osteoarthritis,^{154,155} chronic heart failure,¹⁵⁶ management of spasticity,¹⁵⁷ and other similar conditions. Although the mechanisms are not fully understood, many seasoned clinicians recommend its use.

Theoretically, application of alternating hot and cold water to the body stimulates regulation of sympathetic tone in the extracellular matrix, and generates a "pumping" action that stimulates circulation of blood and lymph. The extracellular matrix is now understood to influence cellular development, movement, reproduction, and shape, as well as biochemical function. Dr. Alfred Pischinger, professor of histology and embryology at the University of Vienna, saw the importance of the extracellular matrix. In 1991, he wrote that the extracellular matrix is the support system for the cell and the foundation substance in which all cells are embedded. The extracellular matrix is made up of collagens and polysaccharides that form proteoglycans. These two molecules form a water-filled, gel-like "ground substance" in

which the connective tissue fibers are embedded. The condition of the space around a cell is as important to health as what occurs within the cell and in the membrane that encloses it.

Supplements

There is a complex set of variables involved in choosing the appropriate supplements for detox patients. Supplement programs should be adapted to the individual patient's need, using the following general strategies:

- Antioxidants for cellular protection
- Amino acids for phase II detoxification
- Chologogues (bile stimulants)
- Bile binding
- Replacing probiotic bacteria
- Repairing intestinal permeability
- Vitamins, minerals, and nutritional cofactors
- Cathartics
- Antiparasitics

Additional tips:

- No supplements during the water fasting except for vitamin C.
- Structuring supplement recommendations for twice-a-day dosing improves compliance.
- Ensure that there is some sort of protein shake for the patient to use, if needed.

Post-Detox Recommendations

After the seven-day program, it is best to continue the hydrotherapy and/or saunas and the supplement strategies for at least a month. The patient should slowly reintroduce foods, starting with foods least likely to irritate the intestinal mucosa. Since the diet is relatively low in essential amino acids, the introduction of eggs, fish, or lean meat on a daily basis helps to restore proper protein balance. After several days of this regimen, begin adding foods that seem prudent for the individual patient; last, introduce known allergens like dairy products, wheat, and soy foods (one at a time and allowing a day or two between each new food to determine any reactions).

Patients may be surprised to discover how well they have adapted to the new diet. Some people experience fewer cravings for many of the foods they gave up during their detox week. The best advice is to support patients to do the best they can throughout this detox

program, following the guidelines as closely as possible but being flexible when necessary. However, patients who are highly allergic to certain foods shouldn't eat them—ever. Eating the right diet is the first step, but digesting it properly is critical for long-term health.

Summary

A home-based detoxification program is within the capacity of many patients, and may generate a significant increase in well being for them. Resting the gut, relaxing the body, the use of heat to release toxic agents, an oligoantigenic diet, and supportive supplementation are all techniques that can be managed at home, provided the patient is given information, advice, and support.

The Gut-Liver Axis

Mary James, ND

Introduction

It is primarily through the gastrointestinal (GI) tract that we “taste” the external environment, including both good and bad. In a healthy system, nutrients critical to health are efficiently absorbed through the small bowel, whereas the bulk of potentially toxic molecules are barred entry. This dual role of the intestine necessitates that this barrier be an incomplete one, which poses a tremendous challenge to the rest of the system. The gut's long list of defense mechanisms, including mechanical, immunologic, and metabolic, speaks to the enormous potential of compounds entering the body to exert toxic effects.

Although enterocytes are separated by “tight junctions” that serve to minimize this potential, a certain amount of passive transfer of particles is normal, and even necessary (e.g., penetration of the intestinal epithelium by enteric antigens is a necessary step in the development of oral tolerance).¹⁵⁸ A variety of factors, however, including exogenous substances, intestinal imbalances, and systemic disease states, can abnormally increase intestinal permeability to the point that toxins and macromolecules overwhelm the body's defense mechanisms and gain entry into the body.¹⁵⁹ Associations between increased permeability (“leaky gut”) and systemic disorders have been well documented for con-

ditions such as inflammatory arthritides,¹⁶⁰ ankylosing spondylitis,¹⁶¹ chronic dermatological conditions,¹⁶² AIDS,¹⁶³ and alcoholism.¹⁶⁴

The likelihood of an adverse outcome depends in part on intestinal factors (e.g., flora balance, mucosal integrity, the type and size of particles presented) and partly on hepatic health and response to these antigens. This is because the liver is the first organ that comes into contact with all enterically-derived molecules, thus playing a crucial role in the metabolism of endogenous and exogenous compounds, as well as the phagocytosis and elimination of immune complexes and other antigenic molecules.¹⁶⁵

Here we see an extraordinary metabolic cooperation between the GI tract and the liver. Abnormal gut permeability (low or high) and/or compromised hepatic function, such as impairments in hepatic metabolism or excessive immunological responses in the liver, can quickly imbalance the gut-liver axis, resulting in systemic toxicity and/or inflammatory responses that contribute to illness.

This part of the chapter will review aspects of this intimate relationship between the gut and liver, briefly highlighting a few of the key clinical disorders resulting from imbalances in this system, specifically in the categories of impaired metabolism and upregulated inflammatory reactions. Finally, it will lay the groundwork for optimal preservation of a healthy gut-liver axis, for both intestine and liver.

The Gut-Liver Axis and Biotransformation

The Role of the Liver

Unlike other organs that receive 100% of their blood supply as arterial, 75% of the liver's blood supply is venous, delivered through the portal vein that travels directly from the intestine, pancreas, and other abdominal organs.¹⁶⁶ Upon arrival at the liver, this venous blood flows through capillary-like vessels called sinusoids to the hepatocytes, the primary functional cells of the liver.

In addition to their other myriad and complex functions, hepatocytes transform gut-derived compounds into safe by-products before excreting them through the bile or releasing them into the arterial circulation. The process of detoxification has been discussed both earlier in this chapter and in Chapter 22;

here, we will review only what is necessary for the discussion that follows.

The detoxification/biotransformation process is mediated by two types of reactions that usually, although not always, occur sequentially.^{167,168} Phase I metabolism serves to biotransform fat-soluble molecules (via oxidation, reduction or hydroxylation) by the cytochrome P450 mixed-function oxidase system. (Most water-soluble drugs and compounds are eliminated from the body through the kidneys). While phase I is a necessary preparatory step for most compounds requiring phase II, its activity concomitantly generates free radicals and renders these compounds into biologically more active forms that may cause damage to surrounding tissues, particularly the mitochondrial-rich hepatocyte that houses this system. In an efficient system, phase II reactions convert these reactive compounds into water-soluble and inactive forms by conjugating them with hydrophilic molecules such as glucuronic acid or glutathione.¹⁶⁹ All of these phase II enzyme reactions are highly dependent upon nutrients, especially sulfhydryl amino acids. Consequently, nutritional deficits, especially when accompanied by upregulated cytochrome P450 enzymes (all of which are inducible by various drugs or xenobiotics), can contribute to toxicity and the accumulation of reactive molecules in the body.

The Role of the GI Tract

The term "first pass" is often applied to the hepatic filtering of exogenous compounds, since the liver inspects all gut-derived substances before releasing them into the systemic circulation. Indeed, most biotransformation reactions in the body take place in the liver. However, given the extensive metabolism that occurs initially in the intestine, hepatic filtering may be more accurately classified as "second pass."

For example, almost all of the hepatic phase I and II reactions occur as well in the intestinal mucosa, serving to minimize the systemic uptake of xenobiotics.¹⁷⁰ The intestinal microflora is also a major player in biotransformation. Many substances that have taken a "second pass" through the liver are returned to the intestine through bile canaliculi for biliary excretion. Some of these compounds are, in turn, reactivated by bacterial enzymes such as beta-glucuronidase, and routed once again to the portal system through enterohepatic recirculation. This normal process serves to recycle essential compounds such as bile acids, estrogen, and vitamin

D.^{171,172} It also ensures the bioavailability of certain sought-after compounds like medications (the eradication of gut microorganisms by antibiotics can reduce the enterohepatic drug recirculation by 8–22%).¹⁷³

Conversely, microbial enzymes may augment toxicity in the body. For example, levels of beta-glucuronidase (elaborated by *Escheriacea coli*, *Bacteroides*, and *Clostridium*)^{174,175} have been observed to be 12.1 times higher in colon cancer patients compared to healthy controls,¹⁷⁶ consistent with the increased reactivation of local carcinogens in the bowel. Animal studies have also demonstrated reductions in breast cancer risk by administering calcium D-glucarate, an inhibitor of beta-glucuronidase.¹⁷⁷ Bacterial azoreductases are able to reduce dietary additives, such as monoazo dyes, into aromatic amines, which can be further metabolized by gut microbes into carcinogens.¹⁷⁸

It is reasonable to assume that enhanced gut permeability would serve to increase the concentration of potentially toxic compounds in the portal circulation, thus burdening the liver's detoxification system. This very premise, in fact, drives ongoing research on the use of the Zonula occluden toxin (produced by *Vibrio cholerae*) for the deliberate induction of leaky gut to enhance drug delivery to the rest of the system.¹⁷⁹

Impaired Hepatic Metabolism and Illness

As mentioned above, reactive intermediates that are generated in phase I metabolism may contribute to illness if not neutralized by subsequent phase II conjugation reactions. The impact of liver disease on hepatocyte function and blood levels of potentially toxic substances can be profound. Inefficient filtering and removal of toxins and bacterial products results in increased delivery of these substances to the systemic circulation. Indeed, elevated levels of circulating gut-derived endotoxin (described below) are often demonstrated in individuals with chronic liver disease.¹⁸⁰

Hepatic Encephalopathy and Neuropeptides

The intimate relationship between the GI tract and the liver is well demonstrated in hepatic encephalopathy (HE). With liver injury, the organ's ability to clear bacterial end products declines and greater amounts of toxic compounds enter the systemic circulation. Some of these compounds are able to pass directly into the

brain and exert neurotoxic effects on the central nervous system.¹⁸¹

Features of hepatic encephalopathy range from confusion to coma. Minimal hepatic encephalopathy (MHE) in patients with liver cirrhosis is a milder form of the disorder that is defined by the presence of otherwise unexplained cognitive dysfunction (only detectable on neurophysiological testing), in the absence of overt hepatic encephalopathy.¹⁸² The disorder is common and can seriously impair a patient's daily functioning.

Observations of developmental regression in some autistic children with intestinal pathology has led to speculation that analogous mechanisms may exist between HE in patients with liver failure and autistic patients who have similar symptoms.¹⁸³

Partial digestion of dietary casein and gluten can lead to the release of "exorphins" (β -casomorphins and gliadomorphins, respectively) that cross the blood-brain barrier and exert opioid-like effects.¹⁸⁴ Here we have an example of a clinical reaction to food proteins that has nothing to do with allergy. Reactions to opiate peptides may also explain some cerebral effects (e.g., gluten-induced schizophrenic symptoms)¹⁸⁵ that cannot be understood from a classical allergy perspective.

Although these biochemical imbalances in autistic individuals are assumed to stem from a breach in the intestinal mucosa rather than from a diseased liver (the case in HE), the net result is the same: the flood of compounds from the gut exceeds the liver's ability to metabolize them, causing neuroactive peptides to escape into the systemic circulation. Consequently, some overlap in therapeutic approaches for autism and hepatic encephalopathy makes sense.

Initially, ammonia was thought to be the driving factor in the pathogenesis of HE and MHE, as it is often elevated in the plasma of patients with liver failure and impaired mental function and it readily diffuses into the brain.¹⁸⁶ Forty percent of ammonia is generated in the intestine from ingested nitrogenous substances and is primarily metabolized in the liver through its conversion to urea.¹⁸⁷

Ammonia's contribution to HE pathogenesis, however, is debatable. First, the actions of ammonia are essentially neuroexcitatory, whereas HE is characterized by an increase in neuronal inhibition, not excitation. Furthermore, blood ammonia levels do not strongly correlate with HE, suggesting that other factors are likely involved.¹⁸⁸ Indeed, numerous gut flora-derived nitroge-

nous compounds, if allowed to enter the bloodstream, have been shown to produce adverse effects on brain function, including false neurotransmitter activity.

One such class of compounds is endogenously-produced benzodiazepine-like compounds, likely synthesized by intestinal bacteria from amino acids.¹⁸⁹ *In vitro* production of gamma-aminobutyric acid (GABA), the major inhibitory neurotransmitter in the mammalian brain, has been demonstrated by *E. coli* and *Bacteroides fragilis*.¹⁹⁰ Other studies have shown the ability of rifaximin (an oral, non-absorbable antibiotic) to lower endogenous benzodiazepine levels by 40%.¹⁹¹

Interestingly, ammonia enhances the activity of GABA receptors, as well as the actions of endogenous benzodiazepine receptor agonists like tetrahydroprogesterone and tetrahydrodeoxycorticosterone (neuroactive steroid derivatives of progesterone and deoxycorticosterone, respectively).¹⁹²

Interventions for HE are usually aimed at reducing gut-derived toxins, especially ammonia. Common recommendations include a low-protein diet, antibiotics directed against colonic bacteria, and the use of non-digestible disaccharides, such as lactulose, which pass through the small bowel without being digested.¹⁹³ Lactulose is conventionally regarded as a treatment for constipation.¹⁹⁴ However, insoluble fibers such as lactulose offer the added advantage of lowering colonic pH through bacterial fermentation, thus creating an environment that discourages the growth of urease-producing microorganisms like *Klebsiella* and *Proteus*.¹⁹⁵

Probiotics are helpful, in part, because the bacterial strains used in these formulations are non-urease-producing. In one study of cirrhotic patients with MHE, a 30-day course of two lactobacillus strains (with or without fiber) was shown to reverse the condition in 50% of patients (13% in placebo group).¹⁹⁶ Fiber, alone, was also beneficial.

The Gut-Liver Axis and Immunologic Responses

The Role of the Intestine

Given the fact that the GI tract encounters more antigens than any other part of the body and must be able to discriminate between invasive organisms and harmless antigens (e.g., commensal bacterial and food

proteins), it is not surprising that the majority of the body's immune system is housed there.¹⁹⁷

The gut-associated lymphoid tissue (GALT) is comprised of lymphocytes in the mucosal epithelium and lamina propria (the underlying connective tissue), mesenteric lymph nodes, and aggregates of lymphoid follicles called Peyer's patches. The intestinal lumen is separated from these lymphoid areas by a single layer of columnar epithelial cells, which is infiltrated by B cells, T cells, macrophages, dendritic cells, and M (microfold) cells. All of these cellular components work in concert to maintain a homeostatic balance between oral tolerance and active immunity.¹⁹⁸

The immunologic fate of orally-administered antigen ultimately depends on where and how antigen is taken up and presented to T cells.¹⁹⁹ Invasive pathogens and other antigens are taken up by M cells, which then pass the intact antigen to antigen-presenting cells (APCs) such as dendritic cells. Alternatively, antigen may enter the lamina propria directly through the villus epithelium. APCs, in turn, present the antigen to T cells in either the Peyer's patch or mesenteric lymph nodes. In the case of pathogens, a microbe-induced inflammatory response leads to full maturation of dendritic cells and release of IL-12, with subsequent induction of T-helper-1 (Th1) cellular differentiation and the release of proinflammatory cytokines.

In the absence of inflammation (as is normally the case with dietary proteins and commensal bacteria), the release of prostaglandin E2, transforming growth factor- β , and IL-10 (an inhibitory cytokine) results in partial maturation of dendritic cells. In the mesenteric lymph node or Peyer's patch, antigen is presented to naïve CD4+ T cells, which differentiate into regulatory T cells. The immunologic consequences are local IgA production and systemic tolerance.^{200,201}

Although the intestinal immune system is clearly capable of generating protective immune responses when necessary, oral tolerance appears to be the default response to antigen. A breakdown in this process, leading to inappropriate immune responses to foods or commensal bacteria, may underlie inflammatory conditions such as Crohn's disease and ulcerative colitis.²⁰²

The Role of the Liver

While hepatocytes assume the responsibility of metabolizing and excreting compounds such as xenobiotics and hormones, it is the monocyte-derived Kupffer

cells in the liver that manage larger compounds such as immune complexes and bacterial products.²⁰³ Kupffer cells represent 80–90% of the fixed macrophage population in the body. Because these cells are situated in the sinusoids of the liver, they are some of the first to come into contact with invading microorganisms and other gut-derived products.²⁰⁴

As macrophages, Kupffer cells act as phagocytes that clear the portal blood of circulating debris, including bacterial toxins. Lipopolysaccharide, a component of gram-negative bacterial cell wall (also referred to as LPS or endotoxin), is one of the most immunogenic toxins in this group.²⁰⁵ Kupffer cells are activated in the process of removing LPS, stimulating in the process the production of inflammatory mediators, including eicosanoids, interleukin-1 (IL-1), IL-6, tumor necrosis factor- α (TNF- α), superoxide, and nitric oxide.²⁰⁶

LPS is not the only bacterial component known to stimulate cytokine synthesis. Components of both gram-negative and gram-positive bacteria, including proteins, glycoproteins, lipoproteins, carbohydrates, and lipids, are also capable of inducing inflammatory cytokines.²⁰⁷

Kupffer cell activation is a normal immunologic response, serving to limit the entry of endotoxins and other antigenic molecules into the systemic circulation. In fact, Kupffer cells are always in a low-grade state of activation due to the small quantities of bacterial toxins that continually penetrate the intestinal mucosa.²⁰⁸ Typically, these endotoxins are not measurable beyond the liver. Only when the ability of the liver to sequester LPS is overwhelmed does endotoxemia occur. Either increased intestinal permeability (with translocation of LPS from the gut) or impaired hepatic clearance (as seen in liver damage) can disrupt this balance, resulting in an exaggerated immune/inflammatory response.

Intestinal permeability increases within hours of exposure to a bacterial toxin,²⁰⁹ further increasing hepatic load. This may be a direct effect of endotoxin on enterocytes or an indirect effect mediated through inflammatory cytokines like TNF- α , blood levels of which are typically elevated following endotoxin administration.²¹⁰ The finding that metronidazole can prevent NSAID-induced hyperpermeability emphasizes the role of bacterial toxins in this process.²¹¹

Endotoxins are capable of producing multiple adverse effects within the liver, ranging from neutrophil accumulation and oxidant stress-induced mitochondrial dysfunction,²¹² to enhanced coagulation,²¹³

reduced bile formation²¹⁴ (hence impaired excretion of waste), and downregulation of cytochrome P450 enzymes.²¹⁵ Although speculated to be a protective effect (upregulated phase I generates potentially toxic reactive intermediates), suppressed cytochrome P450 activity may contribute over time to impaired clearance of xenobiotics from the body.

Endotoxin-induced overactivation of Kupffer cells has been implicated in a number of disorders, including multiple organ dysfunction syndrome, alcoholic and non-alcoholic liver disease, spontaneous bacterial peritonitis, celiac disease, and inflammatory bowel disease. A few of these conditions are reviewed here.

Multiple Organ Dysfunction Syndrome (MODS)

Patients who experience severe trauma frequently develop a significant systemic inflammatory response. In some individuals, this response is followed by progressive deterioration and subsequent failure of various organ systems, a syndrome that has been referred to as “death in slow motion.”²¹⁶ Multiple Organ Dysfunction Syndrome (MODS) is one of the major causes of morbidity and mortality in the Intensive Care Unit (ICU).²¹⁷ Although this inflammatory response and organ failure may develop from uncontrolled sepsis, it is frequently seen without any evidence of sepsis.²¹⁸

Studies have increasingly implicated the gut as an important factor in the pathogenesis of MODS.^{219,220} In fact, a study by Doig and colleagues demonstrated that the only variable statistically associated with the development of secondary MODS in the ICU was increased intestinal permeability on admission or during a patient's stay in the ICU.²²¹ Furthermore, the severity of organ failure correlated with the degree of gut permeability upon admission.

Bacterial translocation from the intestine following multiple trauma and hemorrhage has been documented in animal models, and endotoxemia has been observed during hemorrhagic shock in humans, suggesting that critical illness can directly impact intestinal permeability.²²² Doig's study of ICU patients did not assume a causal relationship between leaky gut and MODS. However, the observed correlation between baseline intestinal permeability and subsequent organ failure supports the premise that gastrointestinal dysfunction may be an important stimulus in the development of the syndrome.

Alcoholic Liver Disease

Increased intestinal permeability is a major factor in the pathogenesis of alcoholic liver disease.²²³ In the intestine, ethanol and its derivatives, especially acetaldehyde, loosen tight junctions between enterocytes, independent of inflammation and nutritional state.^{224,225} Alcohol also favors the growth of gram-negative bacteria, thereby increasing the concentration of endotoxin.²²⁶ As gut permeability increases, endotoxin and other macromolecules activate Kupffer cells. Inflammatory cytokines are released, culminating in hypoxia, neutrophil activation, increased sinusoidal permeability in the liver, and the generation of free radicals.²²⁷ Supporting a strong role for intestinal translocation of endotoxin in alcoholic liver disease, levels of endotoxin-specific IgA have been found to correlate closely with alcohol intake and with levels of SGOT and C-reactive protein (markers of inflammation).²²⁸ Furthermore, ethanol-fed rats are protected from alcohol-induced liver injury when fed, together with ethanol, oral non-absorbable antibiotics, polymyxin (a binder of LPS), or lactobacilli.²²⁹

Hepatocytes contain two primary pathways for the metabolism of ethanol: cytosolic alcohol dehydrogenase and the mitochondrial phase I enzyme, CYP2E1. Alcohol dehydrogenase activity generates NADH, while CYP2E1 converts ethanol to acetaldehyde, producing reactive oxygen species (ROS) in the process.²³⁰ Acetaldehyde can inhibit DNA repair and trap reduced glutathione (GSH), an important peptide for detoxification as well as the neutralization of ROS via GSH-peroxidase (GSH-Px).²³¹ An elevated level of NADH enhances ROS production by altering the intra-mitochondrial redox (reduction-oxidation) potential.²³² Mitochondria are a major source of ROS and contain no catalase (the alternative to GSH-Px for neutralizing peroxides). Therefore, mitochondrial GSH plays a critical role in preserving mitochondrial function. Depletion of GSH in the mitochondria has been shown to sensitize alcohol-exposed hepatocytes to the pro-oxidant effects of cytokines and free radicals generated during ethanol metabolism.²³³

One of the cardinal features of alcoholic liver disease is fatty liver, or steatosis.²³⁴ Various mechanisms, including reduced oxidation of free fatty acids due to mitochondrial damage, have been proposed for the ethanol-induced accumulation of fats in the liver.²³⁵ Fatty acids are highly reactive. Hepatic peroxidation of these lipids results in the generation of potentially toxic intermedi-

ates that further augment inflammatory responses in the liver.²³⁶ Fibrosis is a common reaction to ongoing parenchymal inflammation and injury. If unchecked, cirrhosis can result, characterized by widespread fibrosis, disorganized liver architecture, nodule formation, and dramatic reductions in hepatocellular function.²³⁷

Non-alcoholic Steatohepatitis (NASH)

Non-alcoholic steatohepatitis (NASH) is part of a spectrum of non-alcoholic fatty liver disease (NAFLD) that ranges from simple steatosis (fatty liver) to cirrhosis.²³⁸ NASH, the most common form of progressive liver disease in the United States,²³⁹ is an intermediate state between the two. NAFLD is very common in diabetics and obese individuals,²⁴⁰ including children.²⁴¹

NASH is strongly associated with features of the metabolic syndrome, including insulin resistance, central (visceral) obesity, dysglycemia, hyperlipidemia, and cardiovascular disease.^{242,243} Insulin resistance and obesity both play a role in increased intrahepatic production of free fatty acids from glucose that is not efficiently taken up by peripheral adipocytes.²⁴⁴ High levels of insulin also inhibit mitochondrial fatty acid oxidation, further adding to fat accumulation.²⁴⁵ As described, steatosis sets the stage for liver damage.

Despite the contrasting initial contributing factors (alcohol vs. obesity and insulin resistance), the histologic features of alcoholic- and non-alcoholic liver disease are identical. Hepatocellular injury in both disorders appears to be mediated by lipid peroxidation and oxidative stress.²⁴⁶ Hepatic mitochondria are the main source of this oxidant stress, as beta-oxidation of fatty acids normally produces reactive oxygen species. A vicious cycle develops that involves continual generation of ROS, inflammatory cytokine release, Kupffer cell damage, and depletion of antioxidants.²⁴⁷ Obesity is thought to exacerbate liver injury by sensitizing hepatocytes to TNF- α toxicity and reducing Kupffer cell phagocytosis of toxic debris.²⁴⁸

There are at least two mechanisms by which intestinal bacteria may contribute to liver injury. As mentioned earlier, LPS and other bacterial toxins stimulate Kupffer cells in the liver, resulting in a cascade of cytokines and other inflammatory mediators.²⁴⁹ If chronic, the induced oxidative stress causes hepatic steatosis and fibrosis. Interestingly, bacterial overgrowth in the small intestine has been found in 50% of NASH patients, compared to 22% of healthy controls.²⁵⁰

A second mechanism involves microbe-mediated endogenous production of alcohol and its metabolites. The ability of yeast to ferment sugars into alcohol is well established. Endogenous ethanol production has been documented in various studies and, in some subjects with yeast infection, high ethanol concentrations have been reported following the ingestion of carbohydrate-rich foods.²⁵¹ Yeasts and various gut bacteria have alcohol dehydrogenase activity, thus are capable of oxidizing ethanol to acetaldehyde.²⁵² On the other hand, microbial activity of aldehyde dehydrogenase (converting acetaldehyde to acetate) is limited.²⁵³ As a result, acetaldehyde may accumulate to toxic levels in the face of gut flora imbalances.

Acetaldehyde is a potent toxin capable of inducing leaky gut and systemic absorption of endotoxin.²⁵⁴ As discussed earlier, endotoxin stimulates the release of TNF- α from Kupffer cells. TNF- α further promotes insulin resistance (and subsequent steatosis) in NASH by inhibiting insulin-initiated signal transduction.²⁵⁵ Probiotics may help to reduce levels of acetaldehyde in the gut. Although lactobacilli and bifidobacteria are weak producers of acetaldehyde, they appear to be more efficient than other intestinal bacteria at removing acetaldehyde.²⁵⁶

Hepatic CYP2E1, which is normally induced upon exposure to fatty acids and ethanol, is overexpressed in both NASH and alcoholic liver disease.²⁵⁷ Upregulated CYP2E1 is associated with free radical production²⁵⁸ and the conversion of xenobiotics such as petrochemicals and organic solvents to toxic metabolites, which can contribute to inflammation and fibrosis in the liver.²⁵⁹ Availability of antioxidants is critical for protection.

Celiac Disease

Celiac disease (CD) is a familiar disorder characterized by intolerance to gluten, small bowel mucosal atrophy, malabsorption and abdominal symptoms that are typically reversed by removing gluten from the diet.²⁶⁰ Increased intestinal permeability has been documented in CD,²⁶¹ and has been hypothesized to predispose untreated celiac patients to some of the extra-intestinal symptoms sometimes seen in these patients.²⁶²

Hepatic dysfunction in patients with celiac disease is common. At the time of diagnosis of CD, a mild disturbance of liver function is reported in up to 42% of adults and 54% of children.²⁶³ In most of these cases, elevated liver enzymes tend to normalize within 12

months of gluten removal from the diet. In mild cases where biopsy has been performed, histological changes in the liver are similar to those seen in NASH: Kupffer cell hyperplasia, mononuclear cell infiltration, steatosis, and mild fibrosis. In more severe cases, severe fibrosis, cirrhosis, and chronic hepatitis have been observed in both adults and children.²⁶⁴

Celiac disease is not always apparent in patients with associated liver disease. Elevated liver enzymes may, in fact, be the sole manifestation of CD.²⁶⁵ In one study of adults being investigated for raised transaminases, but without gastrointestinal symptoms, the prevalence of CD was 9%.²⁶⁶ Thirty NASH patients who also tested positive for anti-gliadin antibodies were placed on a gluten-free diet. After three months, both steatosis and serum transaminase levels were reduced. At one year from diagnosis, enzyme levels were normal, intestinal histology had improved, and there was no further evidence of steatosis on ultrasound.²⁶⁷

The exact mechanisms for these associations are unknown, although theories have been proposed. Because a high prevalence of autoantibodies exists in CD patients, the disturbed liver function in this disorder may be mediated by an autoimmune process.²⁶⁸ In many of these individuals, antibodies become undetectable following a period of gluten exclusion. The malabsorption and leaky gut induced by celiac enteropathy have also been proposed to place undue stress on the liver. The fact that cow's milk allergy can induce liver dysfunction in some individuals suggests that it may not be the gluten as much as the mucosal damage that leads to the hepatic injury.²⁶⁹ Other proposed mechanisms include viral triggers²⁷⁰ (hepatitis C is the most common liver disease associated with CD²⁷¹) and genetic predisposition.²⁷²

Because gluten exclusion so often helps to ameliorate hepatic inflammation, testing for celiac disease in patients with liver disorders, and hepatic evaluation in CD patients, would be prudent.

Promoting a Healthy Gut-Liver Axis

As discussed, optimal functioning of the gut-liver axis depends on an intact intestine, as well as a healthy liver that is balanced in both immunologic response to toxins and biotransformation of endogenous and exogenous compounds. A leaky gut places undue burden on the liver, whereas hepatocellular injury enhances the

likelihood of toxic metabolites escaping into the systemic circulation. Consequently, a broad-spectrum approach is fundamental.

Intestinal Support

Gut mucosal integrity can be compromised by a host of factors, including malnutrition,²⁷³ antibiotics,²⁷⁴ small bowel bacterial overgrowth,²⁷⁵ intestinal infections,^{276,277} food allergies,²⁷⁸ gluten intolerance,²⁷⁹ enterotoxic agents such as NSAIDs²⁸⁰ or alcohol,²⁸¹ immune dysregulation,²⁸² mucosal hypoxia,²⁸³ dysmotility,²⁸⁴ and various systemic disorders.²⁸⁵ (For a comprehensive review of intestinal permeability, please see Chapter 28.) What follows is a brief summary of a few key areas that are pertinent to the current discussion.

Nutrition. Enterocytes have one of the highest turnover rates in the body.²⁸⁶ As a result, they are particularly vulnerable to low levels of nutrients that are critical to epithelial cell renewal. One such nutrient is glutamine, the principal metabolic fuel used by cells of the small intestine. Patients given glutamine-free total parenteral nutrition develop atrophy of the intestinal mucosa, impaired immune activity, and leaky gut. Addition of L-glutamine reverses these changes.²⁸⁷

In the large intestine, short-chain fatty acids (SCFAs), specifically n-butyrate, provide energy for the colonocytes and exert a trophic effect on the intestinal lining.²⁸⁸ Although the anaerobic bacterial fermentation of all non-absorbed dietary fibers generates SCFAs, the slower-to-ferment forms (e.g., resistant starch) are generally most effective at raising butyrate levels along the entire length of the bowel.²⁸⁹

Flora balance. Alterations in the complex microflora of the intestine can induce changes that adversely affect intestinal permeability. Those factors that reduce the concentration of beneficial organisms are particularly damaging, such as broad-spectrum (or frequent) antibiotic use. The resulting overgrowth of yeast and gram-negative coliforms may amplify the production of acetaldehyde and endotoxin. As mentioned, endotoxin increases gut permeability and sensitizes Kupffer cells in the liver.

Exposure to stress is associated with reduced levels of beneficial bacteria and decreased production of both secretory IgA²⁹⁰ and protective mucins on the mucosal surface.²⁹¹ Stress stimulates catecholamine release. High concentrations of norepinephrine, in particular, appear

to encourage the growth of possible pathogens in the intestine.²⁹²

Replenishing “friendly” strains of bacteria, such as lactobacilli and bifidobacteria, has been shown to support the gut-liver axis in multiple ways. Probiotics appear to be adaptogenic in the gut. That is, they can stimulate humoral immune responses to pathogens, but also downregulate proinflammatory cytokines when excessive.²⁹³ In cases of bacterial sensitization (and associated gut inflammation), probiotics may help to restore oral tolerance.²⁹⁴ Probiotics have also been shown to reduce levels of acetaldehyde²⁹⁵ and ammonia²⁹⁶ in the intestine, and to help process food antigens. Finally, these organisms have demonstrated a stimulating effect on gastric mucin production.²⁹⁷ Regular ingestion of *Lactobacillus* GG, for example, has been shown to protect the integrity of the gastric mucosal barrier against indomethacin, although it showed no effect at the intestinal level. Prebiotics, such as fructooligosaccharides, can encourage a healthy balance via the selective feeding of bifidobacteria and other beneficial strains.²⁹⁸

Dietary influences. Diets high in meats and meat fat can stimulate the activity of bacterial enzymes such as azoreductase and beta-glucuronidase, high levels of which are capable of producing reactive metabolites in the bowel.²⁹⁹ High amounts of simple sugars in the diet tend to slow bowel transit, thus increasing the exposure of the gut mucosa to potentially toxic compounds; they also promote the production of secondary bile acids in the colon.³⁰⁰

Some individuals are sensitive to large amounts of foods rich in sulfur compounds, principally sulfates and sulfites. These compounds may foster the growth of anaerobic sulfate-reducing bacteria, which reduce the sulfur compounds to hydrogen sulfide. This gas is thought to damage the intestinal mucosa by inhibiting butyrate oxidation, as well as to induce hyperpermeability by degrading mucin.³⁰¹

Continued ingestion of gluten in gluten-sensitive individuals not only predisposes them to malabsorption through microvilli damage, but also to tight junction injury and gut hyperpermeability. Laboratory measurement of anti-gliadin, anti-endomysial, and anti-tissue transglutaminase antibodies can help to rule out the condition.³⁰² Hyperpermeability is also frequently aggravated by ingestion of allergenic foods. This increase is often prevented by the mast cell stabilizer, cromolyn, suggesting that the release of mediators like histamine

and serotonin from mast cells is responsible for the increased permeability.³⁰³ Quercetin, a flavonoid that also reduces gut permeability via mast-cell stabilization, may serve as a natural alternative to cromolyn.³⁰⁴

Small intestine bacterial overgrowth (SIBO). Far fewer bacteria normally inhabit the small intestine compared to the colon. However, factors such as chronic hypochlorhydria or stasis of gut contents can lead to overgrowth of organisms in the small bowel,³⁰⁵ typically coliforms and strict anaerobes.³⁰⁶ SIBO facilitates the translocation of endotoxin and other bacterial toxins from the gut lumen to the portal blood, thereby increasing the risk of liver injury. Interestingly, the prevalence of SIBO in patients with chronic liver disease may be as high as 75%.³⁰⁷

Laboratory Assessment of the GI Tract

Preventive or therapeutic regimens for the gut-liver axis are ideally based on an initial assessment of gastrointestinal function and balance, especially since GI imbalances frequently present without symptoms. Comprehensive digestive stool analysis provides information about several aspects of the gut environment, including flora balance and metabolism (e.g., beneficial bacteria, potential pathogens, yeast, and parasites), as well as digestion, absorption, and immunologic reactions in the gut.

Flora imbalances may also be assessed by measuring specific by-products of microbial activity in a morning urine specimen. The patterns of these organic acids may suggest anaerobic bacterial imbalances, the presence of specific pathogenic organisms, or intestinal malabsorption.

Intestinal permeability and absorption can be assessed by measuring the ability of two non-metabolized sugars—lactulose and mannitol—to permeate the intestinal mucosa.³⁰⁸ Following the ingestion of a challenge drink containing these sugars, their clearance is measured in a urine collection. Mannitol is easily absorbed, thus serving as a marker for transcellular uptake (nutrient absorption). Lactulose is a much larger molecule that is only able to enter the system between enterocytes. Consequently, high amounts of lactulose in the urine, or an elevated lactulose/mannitol ratio, suggest increased intestinal permeability (“leaky gut”). Indirect measures of gut permeability are also available, which include titers of antibody directed against enteric microbial antigens.

Although SIBO is most directly diagnosed through culture of a small bowel aspirate,³⁰⁹ breath testing for SIBO is a more comfortable and cost-effective alternative that still demonstrates good sensitivity. After a baseline breath collection and the ingestion of a lactulose challenge drink, several more breath specimens are collected over a two-hour period. In the laboratory, sequential levels of breath hydrogen and methane are measured and recorded, reflecting bacterial fermentation of the lactulose. An early gas peak (within the first 90 minutes) suggest SIBO. Treatment typically involves the administration of broad-spectrum, anti-microbial agents³¹⁰ and attention to underlying contributing factors such as hypochlorhydria or stasis of gut contents.³¹¹

Hepatic Support

The liver is the largest organ in the body and is extremely complex, with a vast array of metabolic and immunologic functions. The liver’s role in neutralizing and excreting xenobiotics and other potentially toxic compounds is delicately balanced with its immunologic response to bacterial toxins and other macromolecules. As demonstrated, imbalances in either area can lead to toxicity or tissue injury, both local and systemic.

Nutrition. Maintaining adequate broad-spectrum nutritional reserves is of paramount importance for optimal liver function. Numerous amino acids are used in phase II conjugation reactions, and both phase I and phase II reactions utilize a wide array of vitamins and minerals.³¹²

Glutathione, in the form of GSH-S-transferase, helps to process a large number of xenobiotics. GSH-peroxidase helps prevent oxidative stress by catalyzing the reduction of lipid peroxides and hydrogen peroxide.³¹³ Hepatic mitochondria represent a major source of ROS during ethanol metabolism and are also particularly vulnerable to oxidative damage.³¹⁴ Mitochondria do not contain catalase (an alternative means of neutralizing peroxides); therefore, GSH plays a critical role in this organelle. Animal models of NASH typically show reduced levels of GSH.³¹⁵ Availability of GSH depends on sufficient amounts of its constituent amino acids (cysteine, glycine, and glutamic acid), magnesium (an essential cofactor in GSH synthesis), B vitamins for methionine recycling, and reducing agents.³¹⁶

S-adenosylmethionine (SAME) is a major methyl donor and precursor of GSH.³¹⁷ The hepatic form of the enzyme that converts methionine to SAME is highly

vulnerable to oxidative stress.³¹⁸ Low SAME levels have been documented in experimental liver injury, and administration of SAME has been shown to attenuate alcohol-induced liver injury, at least in part by preventing mitochondrial GSH depletion.³¹⁹

Low SAME (hence impaired methylation) is commonly associated with elevated homocysteine.³²⁰ It is interesting to note that increased levels of homocysteine are frequently observed in NASH patients.³²¹ Critical to methionine recycling are adequate levels of vitamins B2, B6, B12, folic acid, and serine.³²² Betaine serves as an alternative methyl donor, and has been shown to increase SAME and also to reduce hepatic enzymes, steatosis, and fibrosis in NASH patients.³²³

Measures aimed at inhibiting the activity of inflammatory cytokines can help to “quiet” an overactive immune response and associated liver injury, such as that found in MODS, alcoholic liver disease, and NASH. Examples of inflammatory cytokine inhibitors include alpha-lipoic acid,³²⁴ zinc,³²⁵ curcumin,³²⁶ and fish oils,³²⁷ all of which act to inhibit NFκB, a transcription factor for inflammatory cytokines and other immune mediators of inflammation.

Fish oils (EPA/DHA), besides modifying prostaglandin-mediated inflammation, have been shown to blunt the systemic inflammatory response to endotoxin.³²⁸ In contrast, corn oil (linoleic acid) appears to increase NFκB activity in activated rat Kupffer cells *in vitro*. When the rats were pretreated with glycine (an agent that inactivates Kupffer cells), this increase was almost completely prevented. The omega-6 fatty acid, arachidonic acid, has been shown to directly induce superoxide production by Kupffer cells.³²⁹

Medium-chain triglycerides (MCTs) appear to benefit the gut-liver axis. In addition to providing immediate energy by virtue of their ability to be absorbed intact across the gut wall and transported into the mitochondria independent of the carnitine shuttle,³³⁰ MCTs are also anti-inflammatory. *In vitro* research has shown that MCTs blunt linoleic acid-induced increases in TNF-α production by ~45%. MCTs also appear to prevent endotoxemia-induced liver damage in mice.³³¹

Lipotropic factors, such as L-carnitine, L-methionine, choline, and inositol, help prevent steatosis by facilitating the oxidation of fatty acids in the liver.³³² These nutrients (often used in combination with liver botanicals) also enhance the flow of bile from the liver and gall bladder, thereby assisting in the removal of

toxins. Phosphatidylcholine (from lecithin) has been shown to protect against alcoholic cirrhosis, enhance collagenase activity, and prevent acetaldehyde-induced collagen accumulation *in vitro*.³³³ Supplementation with pantethine (a derivative of pantothenic acid) may help to reduce the toxic effects of acetaldehyde by increasing the activity of aldehyde dehydrogenase.³³⁴

It is beyond the scope of this book to review the wide array of botanicals that effectively support the liver. The reader is encouraged to consult relevant texts for listings of cholagogues, choleretics, cholagogues, and antioxidant herbs.

Lifestyle. As mentioned, insulin resistance is a common feature of NASH. When glucose is not efficiently taken up by peripheral adipocytes and myocytes, the liver converts this glucose to free fatty acids. Over time, the increased fat deposition contributes to steatosis, the precursor to NASH. Obesity, irrespective of insulin resistance, predisposes to hepatic steatosis by increasing the amount of free fatty acids entering the hepatocyte.³³⁵ CYP2E1 is upregulated by this process.³³⁶ Increased CYP2E1 activity has been demonstrated in type 2 diabetes, insulin resistance, central obesity, and NASH.³³⁷ It is also upregulated by a high-fat, low-carbohydrate diet.³³⁸ Finally, obesity is associated with impaired phagocytic function by Kupffer cells.³³⁹

Dietary adjustments, customized nutritional supplementation, and attention to exercise, weight control, and stress management all impact insulin sensitivity. (Insulin resistance is discussed in Chapter 32, and glycemic control is discussed in Chapter 30.) Stress also directly impacts the development of fatty liver. Adrenal catecholamines directly activate hormone-sensitive lipase, which in turn promotes the release of free fatty acids from adipose tissue.³⁴⁰ In the liver, these free fatty acids contribute to triglyceride accumulation within hepatocytes.³⁴¹

Laboratory Assessment of Liver Function

The functional capacity of the liver to metabolize and clear xenobiotics from the blood can be evaluated by measuring the clearance of specific challenge substances in the saliva and urine. Caffeine is almost completely absorbed by the intestine and metabolized by cytochrome P450 enzymes.³⁴² Comparing its clearance in two sequential saliva specimens provides insight into up- or downregulated microsomal enzyme activity. Inborn tendencies for excessive or impaired enzyme activity in both phase I and phase II pathways and clinical correlations

can be evaluated by examining a patient's blood for genetic polymorphisms. Some key phase II pathways that may be evaluated for polymorphisms include methylation,³⁴³ glutathione conjugation, and acetylation.³⁴⁴ The two-step conversion of cysteine to inorganic sulfate (sulfoxidation) ensures availability of sulfate for the phase II sulfation pathway. Impaired sulfoxidation (a frequent occurrence in neurological disorders such as Parkinson's)³⁴⁵ can be evaluated by measuring these compounds in the blood.

The body's redox balance can be evaluated by examining antioxidants as well as markers of oxidative stress. Fasting blood measurements of GSH and the endogenous antioxidant enzymes, GSH-peroxidase and superoxide dismutase, reflect varying degrees of protection against ROS, while markers such as urine lipid peroxides can reveal oxidative damage in the body.

Finally, variations in the genes that code for phase I and phase II enzymes are known to influence an individual's ability to neutralize toxic compounds. Polymorphisms in these genes have been associated with adverse drug reactions, as well as cancer and other clinical disorders.³⁴⁶ Genomic testing can reveal susceptibility to imbalances in the detoxification system that may promote illness, and provide direction for more customized prevention and treatment of gut-liver axis disorders.

Summary

Functional medicine practitioners are generally appreciative of the concept of leaky gut and its potential impact on organ systems beyond the intestine. What is sometimes overlooked is the exceptionally tight interplay between gut and liver, and how dramatically imbalances in one organ can affect the performance of the other.

Imbalanced intestinal flora, dysregulated gut immune function, and compromised gut mucosal integrity can all lead to alterations in gut permeability. Malabsorption of critical nutrients impacts every organ system in the body, including hepatic metabolism of potentially toxic compounds. Leaky gut places an undue burden on hepatic detoxification and leads to overactivity of Kupffer cells and excessive release of free radicals and fibrosis-promoting cytokines. Conversely, compromised hepatic function can cause gut-derived compounds, including toxic metabolites and neuroactive peptides, to escape into the systemic circulation

and have an impact on far-reaching organs such as the brain. As liver injury progresses, systemic toxicity increases as well. Analyses of disorders such as hepatic encephalopathy, MODS, and NASH have helped to illuminate this close partnership between gut and liver.

Awareness of the interconnectedness and frequency of asymptomatic functional imbalances should inspire healthcare practitioners to evaluate hepatic function in chronic GI disorders and vice versa. Maintenance of a healthy gut-liver axis is not only achievable through a variety of measures, but is critical to long-term health.

Cellular Messaging, Part I

Jeffrey S. Bland, PhD, and David S. Jones, MD

Introduction

Functional medicine provides the model for the new medical paradigm upon which medicine of the 21st century will be based. Core principles of the functional medicine model include the following:

- The predisposition for disease is related to the interplay of antecedents, triggers, and mediators that give rise to an individual's clinical signs and symptoms.
- Individuals are genetically, metabolically, and biochemically unique and their medical care must support a patient-centered, rather than a disease-centered approach.
- Health is a state of positive vitality related to maintenance of a homeodynamic physiology that reflects a balance both between and among internal and external factors.
- Disease in the adult is often the result of a progressive loss of physiological, cognitive, emotional, and physical function and flexibility (that is, loss of organ reserve).

The antecedents of disease in an individual are dictated in part by the unique set of genetic characteristics

derived from the 23 pairs of chromosomes that the individual inherited from his or her parents. Many of these genetic characteristics demonstrate *pleiomorphism*, which means they can be expressed in different ways, depending upon external and internal triggers. The phenotype (health patterns) the individual expresses results from the interplay between the genetic antecedents and the environmental triggers. Triggers include infectious organisms, stress, toxic exposures, electromagnetic radiation, trauma, and—probably most important of all—poor nutrition and activity/exercise patterns. It is now recognized that specific environmental exposures can have an epigenetic influence on genetic expression in the offspring that can be passed on to subsequent generations.¹ This relationship ties genes and environment together in ways that go beyond simple Mendelian genetics.

The mediators released as a result of exposure to these triggers represent a broad array of intercellular communication agents. These can be large and protein-like in structure (e.g., insulin) or small (e.g., the sex hormones). Table 32.1 provides a list of representative intercellular communication mediators, their type, and their function.

Table 32.1 Representative Classes of Intercellular Communication Agents

Communication Agent	Type	Function
Prostaglandins	Small molecules derived from arachidonic acid	Cellular regulators
Leukotrienes and thromboxanes	Small molecules derived from arachidonic acid	Proinflammatory
Nitric oxide	Small molecule derived from arginine via nitric oxide synthase	Immune, neurological, vascular effects
Dopamine, serotonin, acetylcholine	Small molecules derived from tyrosine, tryptophan, and choline, respectively	Neurotransmitters
Cortisol, aldosterone	Small molecules derived from cholesterol	Stress hormones and electrolyte control
Estrogen, testosterone, DHEA	Small molecules derived from cholesterol	Sex hormones
Melatonin	Small molecule derived from tryptophan	Sleep regulation
N-methyl D-aspartate (NMDA), glutamate	Small molecules derived from aspartic and glutamic acids	Excitotoxins
Endorphins	Polypeptide	Pain and immune regulation
Insulin, glucagon, somatostatin	Polypeptide	Blood sugar control
Interleukins, tumor necrosis factor, interferon	Protein	Inflammation process and immune function
NFκB/IκB	Protein	Control of oxidant response
ICAM/VCAMs	Protein	Cellular and vascular adhesion
Leptin	Protein	Appetite control
Vasopressin, ACTH, TSH, oxytocin	Polypeptides	Pituitary hormones
Bombesin, vasoactive intestinal peptide	Peptide	Gut-brain transmitters
C-reactive protein (CRP), serum amyloid A (SAAO)	Protein and protein-carbohydrate complex, respectively	Inflammatory markers
Natriuretic peptides (atrial, brain, and C-type natriuretic peptide)	Peptide	Diuretic, vasorelaxant

In many cases, these intercellular communication agents are produced when a trigger modifies gene expression. Imbalances of these agents in response to a trigger result in various signs and symptoms of dysfunction or illness. These signs and symptoms frequently express across multiple organ systems, because the intercellular communication agents are produced in many types of cells that clinically impact myriad conventional medical specialty domains. A more technical discussion of these processes can be found in Chapter 15. Here, we will focus on understanding the cellular communication process from a more clinical perspective.

Research into intercellular communication and intracellular signal transduction is evolving rapidly. Intracellular signal transduction refers to the way cells modify their function when they are exposed to molecules of intercellular communication. These two related fields of investigation, which have emerged from our increased understanding of genetic structure and expression, have practical clinical applications. A notable facet of the emerging research—particularly to the functional medicine practitioner—is the recognition of the importance of lifestyle, nutrition, and environment in determining which intercellular communication agents are expressed at a particular time from a person's pluripotential “card catalogue” of genes. This rapidly accumulating knowledge base has made it possible in many clinical situations to develop a personalized approach to health care that reflects an individual's genetic uniqueness. Practitioners who evaluate the signs and symptoms associated with imbalanced intercellular communication agents (hormonal, neurotransmitter, and immune-modulating molecules) can develop a program to normalize those agents using specific and individually-tailored lifestyle, diet, nutritional, and environmental interventions.

The Impact of Environment on Cellular Messaging

Chronic Stress as a Trigger for Intercellular Communication Dysfunction

More than 25 years ago, Austrian physician Hans Selye, MD, borrowed the term stress from physics to describe an organism's physiological response to perceived stressful events in the environment.² Stress triggers the *fight or flight* response and the short-term release of glucocorticoids, such as cortisol, from the

adrenal glands. The result is a temporary increase in energy production, at the expense of processes that are not required for immediate survival. An imbalance in intercellular communication agents, therefore, naturally results from this stress response.

A chronic stress response, extended over a long period of time, may produce a variety of age-related pathologies, including increased risk of dementia. In animals (as in human Alzheimer's disease), high cortisol levels correlate with increasing disease severity, which is associated, in turn, with degeneration of the substructure in the brain called the hippocampus.^{3,4} Studies attempting to link high cortisol levels directly with reduced hippocampal volume and consequent loss of cognitive function have begun to emerge,⁵ with the association being particularly strong in depression.⁶ None of the research has yet described the precise pathway by which the effects occur.⁷ In healthy subjects, the link between high cortisol and age-related cognitive decline may not actually be accompanied by brain atrophy.⁸ Clearly, there is much we do not yet know, but there is also a growing body of knowledge that can help clinicians improve patient management.

In a 1998 study, researchers measured cortisol levels in 51 individuals over five to six years and determined whether each person's cortisol level was rising or falling over time. They were able to divide the subjects into three groups: those whose cortisol levels were high and increasing (the *high-stress group*); those whose cortisol levels were moderate but increasing (the *moderate-stress group*); and those with decreasing cortisol levels (the *low-stress group*). The researchers found that individuals in the high-stress group had greater memory impairment than those in the low-stress group.⁹ Magnetic resonance imaging (MRI) and additional memory tests were performed on some of the individuals; the results showed that the six individuals in the high-stress group and the five in the moderate-stress group had 14% lower hippocampal volume than those in the low-stress group. They also had reduced hippocampal energy production. This study supports other investigations that indicate long-term, chronic stress may be damaging to the brain and may increase the risk of Alzheimer's and other neurodegenerative diseases.^{10,11}

A 2005 study reported a “new personality construct,” the type D, which is “characterized by the joint tendency to experience negative emotions and to inhibit these emotions while avoiding social contacts with others.”¹²

The research revealed that both characteristics were associated with greater cortisol reactivity to stress; the author hypothesized, therefore, that “Elevated cortisol may be a mediating factor in the association between type D personality and the increased risk for coronary heart disease and, possibly, other medical disorders.”

In 1995, Licinio, Gold, and Wong¹³ proposed a molecular mechanism for stress-induced alterations in the susceptibility to disease. In this model, they evoked the concept of how stress influences gene expression to describe the origin of *stress-induced* diseases ranging from heart disease to arthritis to cancer. They found that the hypothalamic hormone, corticotropin-releasing hormone (CRH), had gene complementarity with pro-inflammatory molecules (as well as cancer oncogenes); they postulated that events elevating CRH levels could increase the risk of many age-related chronic diseases. This model is consistent with the older view of Axelrod and Reisine, who also stated that CRH regulates release of ACTH, which subsequently influences the adrenal catecholamines and glucocorticoids.¹⁴

Since that 1995 study, elevated CRH has been associated with anxiety and all common manifestations of stress, including fear, startle reflex, decreased food intake, and others.¹⁵ Elevated CRH has also been associated with increased proinflammatory response as a result of secretion of TNF- α , IL-1, and IL-6.^{16,17,18} The link with inflammation is being demonstrated through studies of many different conditions, including alterations in gut motility and mucosal function,¹⁹ ulcerative colitis,²⁰ and endometriosis.²¹

Xenobiotics as a Trigger for Intercellular Communication Dysfunction

As mentioned earlier, stress is not the only environmental modifier of cellular communication agents. Environmental xenobiotics have also been identified as “endocrine disrupters” that can modify intercellular communication and cellular function.²² For example, xenobiotic estrogens (environmental compounds with estrogenic activity), can modify the way a woman metabolizes estrogen. Estrogen is metabolized through three hydroxylation reactions—one at the carbon position 2, one at carbon 4, and the third at carbon 16 in the estrogen structure. Investigators have found that the hydroxylation of estrogen and its methylation at carbon 2 result in an estrogen metabolite that **does not** signal the genes of the mammary cells to engage in prolifera-

tion. The absence of a cell proliferation message reduces the risk of breast cancer. On the other hand, hydroxylation at carbon 4 or 16 results in production of a metabolite in the breast tissue that **does** create potential metabolic changes associated with premalignancy.²³

Environmental pollutants can modify the hydroxylation of estrogen, producing a higher ratio of the 4 and 16 hydroxylated estrogen derivatives that are potentially more genotoxic. Pesticides were found to significantly increase the ratio of 16-hydroxyestrone to 2-hydroxyestrone.²⁴ The investigators suggested that the ratio of 16-hydroxyestrone to 2-hydroxyestrone may provide a marker for analyzing breast cancer risk (prognostic indices) and for generating preventive nutritional strategies and interventions. Subsequent studies have often,²⁵ but not always,²⁶ supported the 2-to-16 ratio hypothesis, although the ability of xenobiotics to disrupt hormone function does not appear to be in doubt.^{27,28}

Environmental xenobiotics may affect the detoxification of estrogen by modifying genetic expression and activity of the detoxification enzymes, which are members of the cytochrome P450 family. Some cytochrome P450 isoforms detoxify estrogen by hydroxylation at the 2 position, and others act at the 16 position. We can speculate that environmental chemicals may modify intercellular communication and shift the expression of genes toward the isoforms of cytochrome P450 that result in production of the potentially harmful metabolites produced by position 16 hydroxylation. This could explain why postmenopausal women with the highest circulating estradiol (E2) levels have the greatest frequency of breast cancer. (Earlier evidence from epidemiological and animal studies indicated a causal relationship between high estradiol levels and breast cancer risk in postmenopausal women.²⁹ However, subsequent research has revealed that these issues are more complex. Studies in women have reported that high testosterone levels may be more accurate than estradiol for predicting older women at risk for breast cancer,³⁰ that increased sex steroid levels do **not** translate into a measurable increased breast cancer risk in postmenopausal women with the CYP1 genotype,³¹ and even that estradiol has either no effect or even a positive influence in breast cancer progression and mortality.^{32,33})

Stress and environmental xenobiotics are just two of many external agents that can influence intercellular communication and either decrease or increase a person's risk of age-related diseases. Common constitu-

ents of the diet, including both macro- and micro-nutrients, can also influence cellular messaging and genetic expression.³⁴

Chronic Infection as a Trigger for Intercellular Communication Dysfunction

Research clearly indicates that infectious organisms can modify intercellular communication and signal transduction, and shift the physiological state toward inflammation and risk of heart disease and cerebrovascular disorders. A few examples include the following:

- Chronic *Helicobacter pylori* infection is associated not only with peptic ulcers, but also with increased heart disease risk.³⁵ Possibly because it upregulates intercellular agents involved with chronic inflammation, chronic *H. pylori* infection represents an independent risk factor for cerebrovascular and ischemic heart disease.³⁶ Interestingly, however, one study compared *H. pylori* patients who had been treated with those who had not, and found that eradication treatment had “no effect on metabolic and inflammatory parameters.”³⁷ Current knowledge does not yet rise to the level of demonstrating a causal relationship, nor does it definitely implicate the inflammatory pathways as the link between *H. pylori* infection and heart disease.³⁸
- Infection with *Chlamydia pneumoniae* has also been associated with increased risk of heart disease and cell signals related to inflammation.^{39,40}
- Individuals with certain genetic susceptibilities, such as the apo E4 allele, have increased risk of expressing dementia (including Alzheimer's dementia) as a consequence of chronic infection with the *Herpes simplex* virus.^{41,42}

All of this information indicates that many substances and external agents can initiate altered cellular communication and signal transduction, which can shift a cell into an alarm state associated with altered function and later-stage disease risk.

The Influence of Nutrients on Gene Expression and Intercellular Communication

In the past, nutritionists and other healthcare professionals believed the only role of macronutrients (protein, carbohydrate, and fat) was to provide calories, with little or no effect on the regulatory cycles of the cell. This assumption is changing rapidly, and practitioners of all

disciplines must be able to adapt their clinical practice to the new information. Research indicates that various amino acids in protein, fatty acids in dietary fat, and certain types of carbohydrate affect cell recognition, receptor site function, and genetic expression. Discovery of novel nuclear receptors is increasing and rapidly gaining biological and medical significance. These nuclear receptors are members of a family of supergenes used to control expression of important genes under different physiological circumstances. Four examples of dietary components that interact with receptors and activate their gene regulatory networks are: specific fatty acids,⁴³ antioxidants,⁴⁴ vitamin A,⁴⁵ and trace minerals.⁴⁶

Fatty acids. Omega-3, omega-6, omega-9, medium-chain, and long-chain fatty acids are known to influence cellular membrane structure and function. As a consequence of altered structure and function of membranes, receptor affinity for intercellular mediators can also be altered, thereby affecting signal transduction. Beyond that, among the most important nutrients serving as intercellular communication agents and influencing the control of gene expression are fatty acids that interact with the peroxisome proliferator activated receptors (PPARs).^{47,48} Different fatty acids, members of the omega-6 or omega-3 families, have different influences on the PPARs, as do their metabolic by-products, prostaglandins, and leukotrienes.⁴⁹ In animal studies, dietary n-3 and n-6 polyunsaturated fatty acids have been found to influence expression of the cyclooxygenase-1 and -2 genes that are involved in prostaglandin biosynthesis⁵⁰ and levels of P21^{ras} protein. These studies demonstrate that dietary n-6 unsaturated fatty acids can upregulate expression of cyclooxygenase-2 and, to some extent, cyclooxygenase-1, which can increase inflammation. On the other hand, n-3 fatty acids did not increase cyclooxygenase-2 activity.^{51,52}

Fatty acids have been shown to positively affect the postprandial lipoprotein cascade in diabetic patients,⁵³ a gene expression pattern that may hold promise for dietary and nutritional treatments that could affect the high rate of heart disease in diabetic patients.

Dietary fat also plays a role in this process via the absorption of fat-soluble vitamins. By its own composition, it can also modify the expression of nuclear receptors that, in turn, can influence, for example, thyroid hormone activity. Some important aspects of this complex pathway are depicted in Figure 32.1.

Figure 32.1 Influence of dietary fat on cell signaling

Studies indicate that DHA, a member of the omega-3 fatty acid family, increases TSH concentration in animals.⁵⁴ Substances that increase PPAR activity improve thyroid function, and this influence may occur as a consequence of the effects of T₃ on induction of enzymes involved with mitochondrial activity.⁵⁵ Some of the effects of T₃ on mitochondrial activity may occur as a consequence of activation of PPARs located in the mitochondrial matrix.⁵⁶

In 1998, investigators of dietary prevention of cancer at the Division of Nutritional Carcinogenesis at the American Health Foundation found that omega-3 eicosapentaenoic acid (EPA, fish oil concentrate) inhibited the expression of farnesyl protein transferase, a critical step in oncogenesis.⁵⁷ EPA, therefore, helped prevent colon tumor development in animals. Subsequent studies by other researchers seemed to identify the effect of the fish oil as an ability to differentially modulate Ras activation, without affecting farnesyl protein transferase.^{58,59} Although the precise mechanisms of action are not yet clear, this research opens the door for improved understanding of the potential role of specific macronutrients as cell-signaling substances in modifying gene expression.

Antioxidants. Control of cellular physiology and response to various external signals are both related to the expression of various substances that interact with the genes. A principal example is nuclear factor-kappaB (NFκB). NFκB regulates a number of genes that are necessary for normal immune responses and secretion of intercellular communication agents involved in the inflammatory process. Included among those agents are

interleukin-2 (IL-2), interleukin-6 (IL-6), and tumor necrosis factor-α (TNF-α). Activation of T lymphocytes to engage in inflammatory response requires at least two signals: one that stimulates an increase in intercellular calcium and another that stimulates enzymatic processes, including kinases.

Similarly, evidence indicates that NFκB is activated by a number of intracellular signals. Hydrogen peroxide and other reactive oxygen species induce T cell signals, and modification of the reduction/oxidation (redox) potential within a cell modifies NFκB activation.⁶⁰ As the cellular environment shifts toward oxidative chemistry and away from a balance between oxidation and reduction, the presence of oxidized species in the cell (including glutathione disulfide and lipid peroxides) increases. Proteins become oxidatively damaged as well, with the production of such proteins as oxidized low-density lipoprotein. This oxidative shift in intercellular chemistry promotes the transcription from the genes of adhesion molecules that participate in the inflammatory process, including the intercellular adhesion molecules (ICAMs), endothelial leukocyte adhesion molecules, and vascular adhesion molecules, as well as cytokines.

Strong evidence suggests that the shift of intracellular redox toward an oxidative state is a principal process that signals the genes to shift their transcription and move into an “alarm state.” Knowledge of the increased level of NFκB associated with oxidative stress and its subsequent association with the expression of cell adhesion molecules and interleukins forms an advancing understanding of how inflammation results from external signals of alarm, infection, or toxicity.

Oxidative signals are capable of inducing NFκB-binding activity. Glutathione is a principal intracellular redox buffering agent that helps protect against oxidative stress. As glutathione is consumed, and glutathione disulfide is produced as a consequence of oxidative exposure, NFκB is activated and gene expression signals are modified toward inflammation and alarm.

A number of antioxidant substances play an important role along with glutathione to maintain proper intracellular redox. One that is under current investigation is α-lipoic acid. R-α-lipoic acid occurs naturally as a prosthetic group in α-keto acid dehydrogenase complexes of the mitochondria. However, investigators have found that α-lipoic acid affects cellular metabolic processes *in vitro* and that it has the ability to alter the redox status of cells and interact with glutathione and

other antioxidants to help maintain redox buffering.⁶¹ Most of the clinical studies to date with lipoic acid have been done with intravenous administration, but the evidence indicates that agents that improve cellular redox, such as lipoic acid and N-acetylcysteine, can reduce inflammatory signaling.

In 1998, researchers conducted human clinical trials with intravenous α -lipoic acid supplementation in the treatment of various types of inflammatory conditions involving altered intercellular communication. Among the conditions studied are alcohol-induced liver damage, mushroom poisoning, metal intoxication, and carbon tetrachloride poisoning. Doses of 600 mg per day of lipoic acid have shown positive therapeutic value in the management of insulin-resistant individuals as well. Lipoic acid has a hypoglycemic effect, and it helps improve insulin sensitivity and lowers the risk of diabetic polyneuropathy in type 2 diabetics.⁶²

Because these processes are associated with NF κ B activation and oxidative stress reactions, the expression of ICAM-1 and VCAM-1, which is induced by TNF- α , is inhibited by increasing activity of glutathione peroxidase and production of reduced glutathione.⁶³ In part, this may explain why glutathione-related antioxidant defense mechanisms help prevent human atherosclerotic plaques.⁶⁴ The influence of antioxidants in preventing atherosclerosis and other diseases of aging may not be as simple as a free radical antioxidant effect. It may, instead, be mediated through a complex interaction of cellular communication agents like NF κ B, their relationship to genetic expression of interleukins and adhesion molecules, and their subsequent relationship to white cell attachment to mucosal surfaces and the origin of disease.

In support of this model, it has been reported that vitamin E inhibits the production of cell adhesion molecules and, therefore, also inhibits the attachment of monocytes to cultured human endothelial cells.⁶⁵ In 1994, researchers found that the cardiac drug probucol (which is known to act as an antioxidant) and N-acetylcysteine also inhibited the elaboration of adhesion molecules and the attachment of monocytes to human endothelial cells.

These studies may provide a mechanistic explanation for the clinical observation that antioxidant supplements help block the loss of endothelial function in healthy subjects with normal cholesterol who have consumed a high-fat meal. In a 1997 randomized clinical trial,⁶⁶ 20

individuals with normal cholesterol, who were presumed to be healthy, were administered one of three breakfasts. They received either a high-fat meal, a low-fat meal, or a high-fat meal following pretreatment with oral administration of 1000 mg of vitamin C and 800 IU of vitamin E. A subgroup of 10 subjects also ate the low-fat meal following the same vitamin pretreatment. High-resolution ultrasound assessed flow-mediated (endothelium-dependent) brachial artery vasodilation, measured as percent diameter change before the meal and hourly for six hours following each meal. In this study, flow-mediated vasodilation fell significantly in the high-fat breakfast group. In the low-fat meal group or the high-fat meal group with antioxidant vitamin supplements, there was no such drop. The same researchers published a similar study in 2003,⁶⁷ demonstrating that dietary interventions (e.g., a fruit and vegetable concentrate)—with or without supplemented phytonutrients—could “reverse the immediate adverse impact of high-fat meals on flow-mediated vasoactivity....”

The authors conclude that a single high-fat meal transiently reduces endothelial function for up to four hours in healthy subjects with normal cholesterol, probably through the accumulation of triglyceride-rich lipoproteins and the subsequent effects on the elaboration of adhesion molecules. This decrease was blocked both by dietary intervention and by pretreatment with antioxidant supplements (vitamin C and vitamin E, in the study described above), and, in another study, postprandial supplementation with vitamin C,⁶⁸ suggesting an oxidant/antioxidant mechanism and the potential interrelationship with NF κ B/I κ B modulation of cellular communication agents such as ICAMs and VCAMs. Reduced superoxide dismutase and glutathione peroxidase activities have also been associated with increased risk of endothelial injury.⁶⁹ This is potentially related to their role in quenching the cellular oxidant superoxide, thereby reducing the contribution of oxidative stress to inflammatory signaling. (This topic is addressed further in Chapter 30.)

Vitamin A. Similarly, vitamin A is required for regulation of various receptors. Investigators at the University of Alabama reported in 1998 that vitamin A strongly interacts with the proinflammatory molecules interleukin-4 and interferon- γ to regulate the expression of an immunoglobulin receptor.⁷⁰ Their data suggest vitamin A may be required, therefore, for the regulation of secretory IgA transport in response to mucosal infections.

Vitamin A has also demonstrated both an ability to inhibit expression of TNF- α and iNOS in animals,⁷¹ and a regulatory effect on human intercellular adhesion molecule-1 (ICAM-1).^{72,73}

Although the mechanisms responsible for the anti-inflammatory effect of retinoic acid are still uncertain, researchers are looking for the underlying explanation.⁷⁴

Trace elements. The trace element zinc also plays a very important role in modifying gene expression through its ability to serve as an intercellular messenger. In animals, zinc deficiency increases the output of hypothalamic neuropeptide Y and may explain why appetite is suppressed in zinc deficiency and why anorexia results.^{75,76}

The trace element selenium is also a powerful signaling agent. In a prospective study in 1998,⁷⁷ investigators at the Harvard School of Public Health and at Harvard Medical School used the level of selenium in human toenails as an indicator of selenium status. (The use of toenail and plasma levels as biomarkers of selenium exposure has been validated in further studies.⁷⁸) In this study, low selenium level was associated with increased risk of advanced prostate cancer in males. This study supports a previous report from the cancer study group at the Arizona Cancer Center in 1963, in which oral selenium supplementation at 200 mg per day significantly reduced the incidence of and mortality from carcinomas of several sites, including prostate.⁷⁹ The importance of selenium in cancer prevention has been validated by numerous additional studies in the intervening years.^{80,81,82}

Selenium is an essential nutrient. One of its major roles is as a component of the antioxidant enzyme glutathione peroxidase, which is involved with the recycling of glutathione disulfide to reduced glutathione. In healthy individuals, glutathione is recycled very rapidly and exists principally in the reduced state. As an individual ages or becomes ill, his/her reduced glutathione level decreases, and the amount of oxidized glutathione disulfide increases. This change in status may indicate an increase in oxidative stress that cannot be accommodated by the existing antioxidant systems.⁸³

Insufficient selenium could be one contributor to reduced antioxidant protection. Although selenium does not participate in this process as an intercellular communication agent, it indirectly relates to the influence of an enzyme engaged in establishing proper cellular reduction/oxidation potential. Redox potential, in turn, has

been found to be an important determinant of intercellular communication. Selenium has also been found to be the central mineral atom in the deiodinase enzyme that converts thyroid hormone T₄ to T₃. As such, its deficiency may play a role in secondary hypothyroidism.

As reported in a 2005 review, "selenium is capable of exerting multiple actions on endocrine systems by modifying the expression of at least 30 selenoproteins. ... Selenoenzymes are capable of modifying cell function by acting as antioxidants and modifying redox status and thyroid hormone metabolism."⁸⁴ The authors point out that the most important factor in selenoprotein expression is selenium supply—a fact that is critically important in thyroid function.

Altered Cellular Communication and the Risk of Various Diseases

The 1998 Nobel Prize in Medicine was awarded to three researchers who discovered the role of nitric oxide in physiology. One of the recipients was Ferid Murad, MD, PhD. At the Fourth International Symposium on Functional Medicine in 1997, Dr. Murad presented information showing that many chronic illnesses are associated with imbalances in nitric oxide production in their early stages.

Nitric oxide (NO) is associated with apparently contradictory actions—both proinflammatory effects and protective influences have been identified.^{85,86} NO, an example of a second-signal messenger, alters levels or types of cellular messengers and can play a key role in triggering effects that are associated with a variety of diseases (cutting across numerous ICD-9 diagnostic codes). According to Dr. Murad in 1996, "NO can be recognized as an intracellular second messenger, a local substance for regulation of neighboring cells, a neurotransmitter in central and peripheral neurons, and perhaps a hormone that can act at distant sites and has been shown to have beneficial or deleterious biological effects, depending on its concentration, the system, and the cellular environment."⁸⁷ In particular, diseases associated with altered nitric oxide elaboration and physiology (both adverse and beneficial) include atherosclerosis,⁸⁸ AIDS,^{89,90} cancer,⁹¹ schizophrenia,⁹² and certain inflammatory conditions.^{93,94}

Nitric oxide has several dichotomous effects within the stages of cancer. Chronic inflammation can lead to production of chemical intermediates, including nitric

oxide, as part of the inflammatory cascade. This process, in turn, can mediate damage to DNA. Nitric oxide also appears to be involved with both tumor-promoting and tumoricidal activities.^{95,96} Understanding the balance and activity of nitric oxide within the context of other cellular communication agents associated with the immune and inflammatory processes may help clinicians develop therapies that focus on ameliorating the cause of the disease.

Grouping dysfunctions on the basis of altered cellular communication may be much more useful for understanding the predisposition to disease than is the categorization of disease from a taxonomic perspective. By understanding the triggers that influence elaboration of intercellular mediators and how these mediators influence signs and symptoms, the clinician may be better able to identify and treat the causes of disease, rather than just the symptoms. Once the nature of the imbalance of the cellular communication agent has been identified and evaluated for activity levels, its function may be improved by modification of lifestyle, environment, nutritional pharmacology, or specific medications. For example, supplemental use of L-arginine and other nitric oxide stimulators or inhibitors appears to modify nitric oxide production under some conditions.^{97,98,99}

Administration of the nitric oxide donor S-nitroso-N-acetylpenicillamine reduced the severity of myocardial injury in animals with experimental atherosclerosis that were fed a high-cholesterol, high-fat diet.¹⁰⁰ Nitric oxide protects against the attachment of leukocytes and monocytes to the vascular endothelium, and it helps prevent the early stages of atherogenesis associated with hypercholesterolemia.¹⁰¹ In an animal model using pigs, L-arginine supplementation as a stimulator of nitric oxide production reduced endothelial inflammation and the elaboration of inflammatory messengers during ischemic episodes.¹⁰²

In a human clinical trial in 1998, 26 patients without significant coronary artery disease, as measured by coronary angiography and intravascular ultrasound, were blindly randomized to either oral L-arginine, 3 g tid, or a placebo. Endothelium-dependent coronary blood flow reserve to acetylcholine administration was assessed at baseline and after six months of therapy. After six months, the coronary blood flow in response to acetylcholine in subjects who were taking L-arginine increased compared with the placebo group. The results reached statistical significance ($p < .05$) and were associ-

ated with a decrease in the plasma level of vascular adhesion molecules and an improvement in patients' symptom scores in the L-arginine treatment group, compared to the placebo group.¹⁰³

Many other diseases associated with aging also exhibit altered nitric oxide dynamics. They include the metastatic events of cancer, inflammatory destruction of the joints in arthritis,^{104,105} glial cell activation and dementia,¹⁰⁶ and vascular and secondary side effects associated with type 2 diabetes.¹⁰⁷ Evaluating altered intercellular communication by looking at nitric oxide alone, therefore, may provide insight into a disease process that cuts across many conditions. That insight can be lost if one examines only the end-stage disease.

Neurotransmitters as Intercellular Communication Agents

The first and second signal messengers of inflammation and cellular adhesion are not the only substances with a relationship to oxidative stress mechanisms and mitochondrial function. An array of biologically active peptides with molecular weights between 1 and 5 Kd also has neurotransmission and neuroregulatory effects and communicates with the immune system. These peptides are predominantly distributed in the nervous system and gut of most animals. The significance of these patterns of distribution is still uncertain, but one possibility is that these molecules represent the interface between the external environment and the internal physiological process. Therefore, they are information molecules that translate external events to the internal environment.¹⁰⁸

Within the brain, the anatomic localization of peptides is most notably associated with those regions concerned with neuroendocrine and autonomic regulation. These neuropeptides cross the blood/brain barrier and, therefore, can influence the activity of both glia and neurons. Before these discoveries, almost no one believed that intact peptides could cross the blood/brain barrier. This erroneous belief was based on unsupported opinions rather than on substantiated data.¹⁰⁹ In the evolution of our understanding of peptides, we now recognize that these small molecular weight, protein-like molecules can be transported intact across both the gastrointestinal mucosa and the blood/brain barrier. Therefore, food-derived, peptide-like molecules may, in fact, influence neurotransmission and immune function through

mechanisms not directly related to allergy or traditional immunoglobulin-mediated processes.^{110,111,112}

It is also now recognized that certain food proteins—including gluten from grains and casein from dairy products—can be partially digested to yield bioactive peptides such as gliadorphin and casomorphin that have opioid-like activities in the central nervous system.^{113,114}

In the 1970s, while she was working at the National Institutes of Health, Dr. Candace Pert discovered peptide binding sites for endorphin substances on the surface of white blood cells. This discovery pointed to a connection between brain chemistry and immune function. From this discovery came a strong impetus for the further development of mind/body medicine, in which the distinction between external and internal influences on physiological, cognitive/emotional, and physical functioning is not as important as the interplay among all these elements.^{115,116}

The field of psychoneuroimmunology developed from this exciting series of discoveries in basic neurophysiology and immunology. The mechanisms by which stress, toxins, thoughts, attitudes, and beliefs influence physiological function and later disease are beginning to find a mechanistic explanation. Figure 32.2 describes the increasing understanding of how cellular communication agents interconnect external phenomenology, as taken in through the senses, with internal physiological function.¹¹⁷

Figure 32.2 Interactions between the nervous and immune systems

Summary

As shown in Table 32.1, there are many representative classes of intercellular communication agents (hormonal, neurotransmitter, and immune-modulating molecules). They are released as a well-orchestrated response to both internal and external factors and stressors, with the clear intent to maintain total organism stability and adaptability. This maintenance of stability is an active process for which the term homeodynamics has been coined from the original model of homeostasis. The responses can be either negative or positive. It has become increasingly apparent that many chronic diseases result from failures in these regulatory processes. As stated by Dr. Gary Darland in Chapter 15: “Evolution has resulted in the elaboration of sophisticated mechanisms to maintain cells (and whole organisms) in an optimal state. The systems are not foolproof. If balance is significantly disturbed, it can be difficult to return to a state of grace.”

Cellular Messaging, Part II—Tissue Sensitivity and Intracellular Response

Jeffrey S. Bland, PhD, and David S. Jones, MD

Introduction

A full exploration of the interface of neurochemical and endocrine function (the neuroendocrine system) would require another book. Because this area is so broad, we will focus on a few topics that are particularly relevant to clinical care and that exemplify the complex actions and interactions characteristic of the neuroendocrine system as a whole. In this chapter, we will primarily address thyroid signaling hormones, stress, adrenal function and the HPA axis, growth hormone and insulin-like growth factor-1, and melatonin in the context of the menopausal female neuroendocrine system.

Establishing a healthy balance of hormonal and neurotransmitter signaling function should include consideration of a number of critical activities and mechanisms: production of the messenger substance; transport of the messenger substance; tissue sensitivity to the message; intracellular response to the message; and detoxification and excretion of the messenger substance. In the previous discussion, we focused on inter-

nal and external triggers promoting the production of the messenger substances. Here, the focus is on transport, tissue sensitivity, and intracellular response to the messenger substance and to some specifics of detoxification and excretion of messenger molecules.

We have chosen our topics very deliberately; thyroid signaling hormones, stress, adrenal function, and the HPA axis illustrate the dynamic interplay among the functional factors that create balance or imbalance within endocrine system signaling. Clinicians too often consider only one or two of these factors in developing a patient-management strategy. A clinician who measures the level of a specific messenger substance in a biological fluid and finds it to be low, often makes the assumption that this substance should be replaced with exogenous hormone or neurotransmitter repletion, either natural or synthetic. However, the low level of a substance may, in fact, reflect a series of disordered feedback steps related to transport, tissue sensitivity, and metabolism. Supplementing the substance without inspecting these other factors may aggravate the imbalance, producing even more dramatic signs and/or symptoms. The converse is also true. When a substance is present in an elevated level in a biological fluid, one might assume too much is being produced and an antagonist is needed to block its secretion or function. This assumption might also be inappropriate. Excess production of the substance may be a consequence of reduced tissue sensitivity, as in the case of the hyperinsulinemia/insulin resistance syndrome.

Assessing and Balancing Neuroendocrine Mediators

We will explore ways of assessing the symphony of various neuroendocrine mediators. Developing various approaches to normalizing their balance might involve the use of secretagogues, hormone precursors, hormones themselves, tissue-sensitizing substances, agents that improve bioavailability and/or transport of the substance, or substances that initiate improved metabolism and excretion. As noted in the previous essay, healthy neuroendocrine balance is a very complex issue.

In an ideal world, we would base our understanding of neuroendocrine function on the results of large prospective studies in which a comprehensive panel of neuroendocrine mediators had been measured sequentially throughout the course of a large cohort of representative

individuals' lives, recording as well the changes in health patterns during the study. We would have measurements of thyroid congeners, cortisol, dehydroepiandrosterone, progesterone, estrogen, testosterone, estrogen and testosterone metabolites, melatonin, growth hormone, insulin-like growth factor-1, noradrenaline, serotonin, dopamine, leptin, and tumor necrosis factor- α (TNF- α), over decades of living and a variety of circumstances. Using this information, we could understand the relationship of neuroendocrine modulators to central questions of healthy or unhealthy aging. Unfortunately, in this less-than-ideal world, these studies have not been done. Therefore, our assessment will necessarily depend on a variety of inferential and incomplete data that we must weave together to guide us in making decisions to support healthy aging, vis-à-vis hormonal, neurotransmitter, and immuno-modulating messaging molecules.

A Changing View of Neuroendocrine Signaling and Hormone Balance

Indeed, data from the hypothetical prospective studies described above may never be available. Even if they were, the conclusions that could be drawn *for a specific individual* would likely be equivocal because of the unique variations in his/her polymorphisms and resultant physiology and biochemistry. From midlife on, individuals, in consultation with their healthcare provider(s), make decisions about managing their health concerns based on less-than-complete information. These therapeutic plans are often based on the assumption that aging is a disease process and can be managed like illness (single disease with a focused pharmacological intervention). However, according to the model presented in this book, to assess neuroendocrine function, we must take into account the web-like interaction of multiple messaging processes that cut across discrete organ systems and function through complex feedback control systems.

Using this model, we should, for example, view estrogen and progesterone not solely as reproductive hormones in the female, but rather as signaling substances that also affect function in the central and peripheral nervous system,¹¹⁸ the musculoskeletal system,^{119,120} adipocyte physiology, and immunological response.¹²¹ Receptor sites for steroid hormones have been identified on the surface of virtually every type of cell in the body.¹²² It would, therefore, be safe to say that steroid hormones represent a component of the

body's overall cell signaling processes and influence the way tissues, organs, and organ systems respond to their environment.^{123,124}

Our perception of neuroendocrine function is rapidly changing. Within the past decade, many nuclear receptors have been identified, along with a series of agonist and antagonist substances—hormone transporters whose important physiological function had previously not been recognized.^{125,126,127} For example, we have moved beyond the belief that the steroid-based endocrine system is principally the sex steroid hormone-modulated pathways.^{128,129} We now understand the importance of an array of collateral activities of substances, including dehydroepiandrosterone, omega-3 fatty acids, and lipoic acid. This improved understanding of neuroendocrine mediators will help clinicians design programs to balance function and promote healthy aging. Function of the endocrine system plays a central role in defining many aspects of the natural, biological aging process.

Also, woven into this complex interchange is the oxidative/reductive balance of the system. The process of free radical production can damage mitochondrial DNA, which is approximately 10 times more susceptible to oxidative damage than nuclear DNA, and the majority of oxidants are produced in the mitochondria. As mitochondrial DNA (mtDNA) undergoes injury, the daughter mitochondria become less able to provide energy production for the cell, and redox imbalances result. These imbalances can be seen as altered cell messages that may affect both neuroendocrine and immune functions. These alterations can act as feed-forward mechanisms leading to unhealthy aging, with changes in neuroendocrine function resulting in altered cellular energy production. This, in turn, produces more free radicals, further damaging mtDNA, and thus continuing the “aging” of the neuroendocrine system.

The contribution of neuroendocrine imbalance to aging may be, in part, a manifestation of a fundamental process of altered reduction/oxidation potential within the mitochondrion, creating cellular messages that alter the expression of the genome. As cellular physiology changes, different messages are expressed from the genome, cellular debris accumulates, and the immune system may become sensitive to the body itself. The result can be autoimmune disorders. Autoimmune diseases like rheumatoid arthritis, systemic lupus erythematosus, and myasthenia gravis are immune dysfunctions

associated with alteration in neuroendocrine function that increase in prevalence with age and are associated with unhealthy aging.

In the early 1990s, a study from the University of Pisa in Italy reported that healthy centenarians had serum plasma titers of thyroid autoantibodies similar to controls aged less than 50.¹³⁰ This observation, and other supportive research, suggests that one principle of healthy aging is to avoid becoming “allergic to yourself” by lowering the load of antigenic substances that generate immune vigilance and cross-reactivity with products of the endocrine glands.

No single explanation to adequately address all aspects of biological aging has been developed.¹³¹ The recognition is emerging that accelerated biological aging occurs in concert with a variety of physiological changes in the immune, endocrine, musculoskeletal, neurological, and cardiovascular systems. All these changes may interrelate with fundamental processes at the cellular level, altered gene expression, modification of intracellular reduction/oxidation balance, and alterations in neuroendocrine messaging.

Neuroendocrine System as Indicator of Cellular Changes in Aging

The neuroendocrine system may be a barometer for changes occurring at the cellular level that reflect aspects of the aging processes. Changes in neuroendocrine function may reflect underlying alterations in cellular physiology associated with unhealthy aging, rather than these changes themselves being the primary cause of aging. The inclusion of these interactions brings us full circle in the development of a more complete model of neuroendocrine and immune system interchanges. Often, it is not possible to establish cause/effect relationships; but it is clear that changes in neuroendocrine function throughout life are associated with significant changes in physiology and vitality.

Therefore, in this chapter we will address the neuroendocrine system, not as the primary seat of aging, but as a reflective component of the overall process of the body and its various rhythms associated with functional status. We should not assume a neuroendocrine system that will promote healthy aging in a 50-year-old is the same as that required for health in a 15-, 25-, or 35-year-old. Changes in endocrine function occur throughout life and are orchestrated by the temporal characteristics of gene expression. These functional

changes may have specific advantages at specific times. For example, aggression is often associated with youthful males whose androgenic hormone levels are typically much higher than in older-age males for whom reason, judgment, and control of passion become dominant survival features. Characteristics advantageous in youth for reproduction and protecting the young may become disadvantageous in older age when reproduction is not vital and maintaining function becomes more important. Thus, it is important to evaluate neuroendocrine system function with the objective of achieving healthy balance for individuals of a specific age.

The neuroendocrine system translates sensory input from the environment into physiochemical actions that modify the phenotype. Complex interactions take place among all the organs involved in neuroendocrine function. One should be cautious in evaluating neuroendocrine function based on simple, single-point analysis of one component of this web. There is a certain rhythmic pattern to neuroendocrine function, with cycles that are daily, monthly, yearly, and even longer. These cycles may be tied to environmental events such as the full moon, solar spots, and perhaps even low-level electromagnetic fields. All these complexities make evaluation of neuroendocrine function challenging. Taking a single blood or saliva sample of two or three hormones and trying to understand the rhythmic nature of endocrine balance in the individual may be overly simplistic and can lead to inappropriate clinical decisions.

Evaluating Thyroid Function

A common clinical presentation of patients with age-related functional changes of the neuroendocrine/immune system is *altered thyroid function*, although a number of studies have demonstrated that in the elderly the clinical picture is often atypical and misattributed to aging or disease.^{132,133} We have chosen this system to more fully illustrate the model of a functional neuroendocrinological investigation. Typical symptoms of low thyroid function include low energy, cold hands and feet, fatigue, hypercholesterolemia, muscle pain, depression, and cognitive deficits, although in the elderly these complaints can also be related to cardiovascular, gastrointestinal, and neuropsychiatric disorders.¹³⁴ The conditions of either hypo- or hyperthyroidism¹³⁵ are often related to altered thyroid hormone sensitivity and cellular response.

As mentioned earlier, maintaining thyroid hormone function throughout the aging process may be an important hallmark of healthy aging.^{136,137} In 1992, a group of investigators from the National Research Council in Italy performed a series of studies to examine the thyroid's importance during aging. They compared parameters of thyroid function in 34 healthy centenarians, ranging in age from 100 to 108 years, to that of 40 younger subjects, aged 70 to 85. They found a significantly lower level of thyroid antibodies in the sera of healthy centenarians than in the sera of 75- to 80-year-olds who had varying degrees of chronic illness. This observation led the authors to suggest that the absence of circulating thyroid autoantibodies in healthy centenarians is not mere coincidence.¹³⁸ Since unhealthy aging is associated with a progressively increasing prevalence of organ-specific and non-organ-specific autoantibodies,^{139,140} the absence of these antibodies may represent a reduced risk in older age for cardiovascular disease and other chronic age-related disorders,¹⁴¹ and therefore could be a hallmark of age-related healthy neuroendocrine-immune signaling.

Subclinical Hypothyroidism: A Case Report

Subclinical hypothyroidism represents, for many individuals, the first signs of thyroid hormone dysfunction. A case report in *The New England Journal of Medicine* in 2001 described a 59-year-old woman in whom routine screening revealed serum thyrotropin (TSH) of 7 mU per liter. (Normal reference range for this case study was reported as 1-5 mU per liter.) Her symptoms, although mild, had been present for more than 10 years.

The results of the physical examination were normal, except that her thyroid was small and firm, with a slightly irregular surface. Her serum cholesterol level was 220 mg per deciliter; her low-density lipoprotein cholesterol was 140 mg per deciliter; and a test for antibodies against thyroperoxidase (TPO) was positive. She had difficulty losing weight. The author of this clinical case presentation, David S. Cooper, MD, asked if treatment with thyroxin replacement therapy should be initiated in this patient.¹⁴² The answer to this was a conditional "yes."

From a functional medicine perspective, that answer begs the question of how to more fully assess a patient with a diagnosis of borderline subclinical thyroid dysfunction before asking the downstream question about hormone replacement therapy (HRT). This patient may be at risk for age-related chronic diseases as

a consequence of imbalances in the hypothalamus/pituitary/thyroid axis; the antecedents and triggers to her elevated TSH require further elucidation. Recent evidence suggests that jumping into thyroid hormone replacement therapy before thoroughly evaluating thyroid hormone metabolism may be inappropriate.^{143,144} Additionally, a placebo-controlled trial of the administration of 100 mg of L-thyroxine to patients who expressed symptoms of borderline hypothyroidism (*cf.* this 59-year-old woman) found thyroxine HRT to be no more effective than placebo in improving cognitive function, mood, or well being.¹⁴⁵

Low serum TSH level in conjunction with normal concentrations of circulating thyroid hormones is associated with increased mortality from all causes in people 60 years or older.¹⁴⁶ This does not necessarily mean that the increased mortality is related to a primary hypothyroidism requiring thyroid hormone replacement. The increased mortality may reflect altered hypothalamic or pituitary function or alteration in metabolism or cell signaling of thyroid hormones at the peripheral tissue. The diagnosis of low serum TSH is simply a first step in the much more complex evaluation of function within this system.

Laboratory Thyroid Screening

Laboratory blood testing has often been used as the *sine qua non* in determining hypo- or hyperthyroidism in a patient. The TSH test (aka: thyroid-stimulating hormone or thyrotropin hormone test), free T_4 , free T_3 , and thyroid peroxidase activity (TPO) tests have become a routine part of a panel for evaluating primary and secondary thyroid hormone dysfunction.¹⁴⁷

Considerable controversy exists regarding whether the laboratory in and of itself can define borderline thyroid dysfunctions^{148,149} and, if so, what is the most sensitive analyte(s) to evaluate. A study in 2001 evaluated TSH concentrations as a potential first-line test of thyroid function. Using a combination of TSH and thyroxine (free T_4) assays, investigators analyzed 56,000 tests for a population of 471,000 people over a period of 12 months. The study identified 17 patients with secondary hypothyroidism whose thyrotropin concentrations were within the normal reference range (0.17-3.20 mU/L). In most cases, TSH proved useful for evaluating pituitary function regulation of thyroid hormone secretion from the thyroid gland. But in this study, it did not pick

up secondary hypothyroidism and related disorders, such as thyroid hormone resistance.¹⁵⁰

Baisier and colleagues suggest the 24-hour urinary excretion of free T_3 may also prove beneficial in defining patients with functional borderline hypothyroidism.¹⁵¹ However, these authors agree that the evidence indicates TSH measurement, free T_4 , and serum free T_3 all have clinical limitations in their ability to identify all cases of thyroid hormone dysfunction.

Cardiac laboratory thyroid screening. In subclinical hypothyroidism (SH), impaired diastolic function has been documented at rest and on effort, while systolic dysfunction has only been assessed on effort. A study was performed to further assess systolic function at rest in SH and to ascertain whether cardiac dysfunction could precede TSH increase in euthyroid patients with a high risk of developing SH. All subjects underwent pulsed wave tissue Doppler imaging (PWTDI) to accurately quantify the global and regional left ventricular function. PWTDI proved to be a sensitive technique that allowed detection of both diastolic and systolic abnormalities, not only in patients with SH, but also in euthyroid subjects with a high risk of developing thyroid failure. Furthermore, the significant correlations of several PWTDI indices with serum free T_3 and TSH concentrations strongly supported the concept of a continuum of slight thyroid failure in autoimmune thyroiditis extending to subjects with serum TSH still within the normal range.¹⁵² Other studies in the cardiac laboratory have substantiated the importance of these cardiac lab modalities in the evaluation of SH.¹⁵³

Alternatives to laboratory testing. According to Damien Downing, MD, an important clinical adjunct is to approach functional thyroid problems from careful evaluation of the patient, not simply treating the laboratory test. The combination of good clinical acumen and a functional assessment based on patient-centered review, combined with laboratory information, provides a much more robust and reliable review of dysfunctions of the hypothalamic-pituitary-thyroid (HPT) axis.¹⁵⁴

Additional criteria for evaluating thyroid dysfunction. The following nine symptoms appear to be among the most reliable indicators of dysfunction in the HPT axis:

1. Fatigue, usually persistent, especially on waking; less toward the evening, with slow recovery
2. Depression; psychological melancholia with a tendency toward depression

3. Coldness, deep as well as peripheral
4. Elevated cholesterol, generally seen as LDL cholesterol increases
5. Muscle cramps and pain in the calves, thighs, and upper arms
6. Constipation: hard bowel movements and decreased frequency (at most, every two days)
7. Arthritis; rheumatoid-like pain in the joints, muscle swelling, and muscle pain
8. Neurological symptoms, such as prolonged Achilles tendon reflex time
9. Easy bruising and/or evidence of clotting defects^{155,156,157}

Using this extended list of clinical signs and symptoms associated with dysfunction of the HPT axis,^{158,159} it is possible to hypothesize that subclinical hypothyroidism may be more common in a population of patients with early signs of age-related diseases than most practitioners realize. For example, elevated TSH concentrations have reportedly been found in nearly 10% of women older than 60 years.¹⁶⁰

Prevalence of Subclinical Thyroid Dysfunction

It is apparent from this discussion that subclinical thyroid dysfunction is common in individuals with symptoms of unhealthy aging. It may be seen across a number of organ systems, including peripheral nerve dysfunction, depression, increased seasonal affective disorder (SAD), memory deficits, elevated LDL levels and risk of atherosclerosis,^{161,162} skeletal muscle problems including pain, sarcopenia, and fibromyalgia, and exacerbation of allergic disorders and sleep problems.

Thyroid dysfunctions are related not only to the primary thyroid gland, but also to a range of secondary metabolic challenges associated with unhealthy aging and poor nutritional status, all of which reduce the efficiency of the HPT axis and control of intermediary metabolism and cellular physiology by thyroid hormones.¹⁶³ Furthermore, high levels of cortisol, along with high levels of inflammatory cytokines, have been associated with depressed levels of the active thyroid hormone T_3 in fibromyalgia patients, suggesting they may down-regulate the activity of the HPT axis.¹⁶⁴ Increased urinary cortisol metabolites have been associated with reduction in peripheral thyroid hormone metabolism and symptoms of functional hypothyroidism as well.¹⁶⁵

Stress increases the levels of glucagon, lowers levels of T_3 , and elevates levels of rT_3 , producing the outcome of secondary borderline hypothyroidism.¹⁶⁶ Reports have indicated that thyroxine replacement therapy in patients with neuromuscular symptoms and subclinical hypothyroidism can result in improved function.¹⁶⁷ Therefore, psychological, chemical, and physical stresses have a significant impact on the HPT axis and may account for the high prevalence of functional thyroid problems in aging individuals.

Effects of Maternal Thyroid Dysfunction

Abnormalities in TSH, T_4 , and T_3 are often related to depressive illnesses and melancholia.¹⁶⁸ Thyroid hormones play an important role in the development of the nervous system in the fetus, as well as in neonates and children. Hypothyroidism in the pregnant woman or low thyroid function in the neonate can have a long-term impact on the child's behavior, locomotor ability, speech, hearing, and cognitive function.¹⁶⁹ T_3 reportedly stimulates gene expression of myelin basic protein in oligodendrocytes.¹⁷⁰ Therefore, data suggest that in the developing central nervous system, thyroid hormones regulate processes of terminal brain differentiation, such as dendritic and axonal growth, synaptogenesis, and myelination.

Iodination of Thyroxine and Related Biochemical Processes

Thyroglobulin is a precursor of all thyroid hormone and contains approximately 110 tyrosine residues. These residues are iodinated by a peroxidase enzyme that ultimately forms the thyroid hormones. The iodination of thyroxine by the peroxidase enzyme depends on the availability of adequate dietary iodine, as well as active thyroperoxidase (TPO). Iodide is actively transported from the extracellular fluid into the thyroid follicular cell.

Substances such as thiocyanate and sulfhydryl compounds (e.g., 5-vinylloxalidine-2-thione) inhibit thyroid hormone by blocking the iodination of thyroglobulin. A number of dietary sulfhydryl compounds may, when an individual consumes them at high levels, have similar adverse impact on the iodination of thyroglobulin. These compounds include members of the Brassica family of vegetables: cabbage, Brussels sprouts, broccoli, and cauliflower.^{171,172,173,174}

It is important to point out, however, that the level of intake that renders these phytochemicals “goitrogenic” is higher than individuals would get in their normal diet. Most studies have been performed in animals with high intake levels and using uncooked vegetables. Although there are some anecdotal reports of women developing goiters after consuming large amounts of cabbage juice, human studies provide no clear evidence that normal intake of the Brassica family of vegetables induces thyroid abnormalities.

Once iodinated tyrosine residues in thyroglobulin have been formed, there is a coupling of these molecules to produce the principal thyroid hormone thyroxine (T_4). Secretion of T_4 and, to a smaller extent, T_3 from the thyroid gland, depends on TSH stimulation from the pituitary gland, which takes its message from stimulation by thyrotropin-releasing hormone (TRH), secreted by the hypothalamus. Stressors that influence the function of the hypothalamus and pituitary system, therefore, influence not only the secretion of catecholamines and glucocorticoids from the adrenal gland, but also thyroid hormone and its metabolism.

Thyroxine (T_4) represents the majority of the thyroid hormone secreted by the thyroid gland. T_3 , which is the more active thyroid hormone, is produced principally by deiodination reactions at the peripheral tissues through the activity of the 5'-deiodinase enzyme. The iodine atom can be removed from T_4 in one of two ways: producing that result via the type 1 and type 2 deiodinases results in active T_3 ; the deiodinase type 3 pathway results in an inactive rT_3 . Deiodination of T_4 to T_3 through type 1 deiodinase requires an adequate level of selenium nutrition, because this enzyme is a selenoenzyme.

On a relative scale of biological activities, T_3 is three to eight times more active than T_4 in influencing physiological function, and rT_3 has less than 1% of the activity of T_4 . T_3 , therefore, is considered a “step up” hormonal message, whereas rT_3 is considered a “step-down” hormonal message. Psychosocial, chemical, and physical stressors increase the production of rT_3 through the activity of deiodinase type 3, at the expense of lowering the physiologically active levels of T_3 .¹⁷⁵

To be active, T_3 must both bind to one of its receptors in the cell, and the receptor- T_3 complex must then bind and activate specific DNA sequences in the cell's nucleus, which are present on T_3 target genes.¹⁷⁶ The activation of the T_3 -nuclear receptor-transcription

depends on heterodimerization of T_3 receptors with retinoic acid-specific receptors, and therefore may be dependent on vitamin A nutrition and metabolism.

Molecular Biology of Thyroid Hormone Action

Our understanding of the molecular biology of thyroid hormone action is improving. We know it is mediated by multiple thyroid hormone receptor isoforms derived from two distinct genes. The thyroid hormone receptors belong to a nuclear receptor super-family that includes receptors for other small hormones such as vitamin A-derived retinoic acid and vitamin D-derived 1,25-dihydroxy vitamin D.¹⁷⁷

The appropriate conversion of T_4 to T_3 , transport of T_3 to specific cells, the binding of T_3 to receptors within these cells, and the binding and activation of unique regions of the genome are important in establishing proper thyroid hormone-mediated function. This is another example of the important role of modulator substances on genomics and proteomics. It once again emphasizes the importance of nutrition and environment in modifying gene expression and cellular physiology. Nutrition and the environment can play multiple roles in modifying thyroid hormone metabolism, activity of the HPT axis, sensitivity of the hormone at the receptor site, and its ultimate effect on cellular transcription.

The peripheral metabolism of T_4 to T_3 occurs principally in the liver. Low levels of circulating T_3 with high or adequate levels of T_4 have been associated with such conditions as the “euthyroid sick syndrome,” or the “low T_3 syndrome.”¹⁷⁸ We might consider T_4 a “prohormone” that must be converted to T_3 to have its full physiological functional impact on cellular physiology.¹⁷⁹ Because of their important role in deiodinating T_4 to T_3 , the thyroid hormone deiodinases have been called the “gatekeepers” of thyroid hormone action.¹⁸⁰ Selenium deficiency may reduce the function of this enzyme and result in lowered T_3 production.

Effects of Soy Consumption on Thyroid Function

Isoflavones from soy have been found to be iodinated by TPO and it was therefore hypothesized that they might compete with thyroglobulin as sites for iodination. Further studies have shown conflicting results. A high level of soybean intake in animals has been implicated in diet-induced goiter in a number of

studies. *In vitro* incubation of soy isoflavones with TPO shows that the isoflavones can compete with thyroglobulin.¹⁸¹ Genistein, the principal isoflavone found in soybeans, is known to inactivate TPO *in vitro*, but in animal studies it did not induce an apparent hypothyroid effect. In contrast, rats that consumed a diet supplemented with genistein at up to 500 parts per million showed no difference in levels of T_3 , T_4 , and TSH compared to rats on a non-soy diet.¹⁸²

In one clinical observation study, when a group of adult humans had a high daily intake of soybeans (30 g per day), half of those on the three-month program experienced such hypometabolic symptoms as malaise, constipation, sleepiness, and goiters. No differences were seen in thyroid hormone levels, and the symptoms were shown to disappear within one month after soybeans were removed from the diet. In a subgroup of these subjects, dietary iodide levels were lower during the administration of soybeans, and TSH levels were increased.¹⁸³

Information from both animal and human studies seems to suggest that as soy isoflavones are increased in the diet, a reasonable precaution is to also increase iodide in the diet. Iodide is available either in organic sources, such as seaweed, or in inorganic form. Soy isoflavones and thyroid function may be of clinical concern in the use of soy formulas in the first years of life. Increased intake of isoflavones may be contraindicated for infants who already have hypothyroid symptoms.¹⁸⁴ Reports indicate that increasing soy consumption can reduce the absorption of exogenous thyroid hormone administered to infants who have thyroid dysfunction.¹⁸⁵ This is not a consequence of the adverse effect of soy isoflavones on thyroid metabolism; it is a consequence of soy's impact on the absorption of exogenous thyroid that has been orally administered as a medication. Many individuals have expressed strong concern that infants with hypothyroidism who received soy formula may have exacerbation of their thyroid symptoms and that the use of soy-based formula should be approached cautiously.¹⁸⁶

This information suggests that normal levels of intake of soy isoflavones such as genistein are not "goitrogenic," but adequate dietary levels of iodide and selenium should be maintained while one consumes these isoflavones to support proper hormone production and metabolism. One study in 2003 demonstrated that soy isoflavones did not adversely affect thyroid

function in iodine-replete subjects.¹⁸⁷ And, for individuals on exogenous thyroid supplements, thyroid hormone should be monitored when a person changes to a high soy protein-supplemented diet.

Other Thyroid Hormone Antagonists

More important than the soy isoflavones in terms of thyroid metabolism are specific bioflavonoids, which, if given at high levels on a continued basis, have been shown *in vitro* and in animal studies to demonstrate antagonistic effects on both TPO and the iodinase enzymes, thereby lowering thyroid hormone activity.^{188,189,190} It has come to light that certain types of flavonoids derived from plant foods may participate as inhibitors of T_4 production. Studies indicate a "pro-hormone" variety of flavonoids, including fisetin, kaempferol, naringenin, and quercetin, have the ability to inhibit TPO.¹⁹¹ As noted above, TPO is involved in the iodination of thyroglobulin, after which T_4 is produced from the iodinated thyroglobulin.

One other recently identified antagonist of thyroid hormone metabolism is L-carnitine. One study demonstrated that supplementation with L-carnitine at the level of 2 to 4 g/day provided successful treatment of patients with hyperthyroidism.¹⁹² L-carnitine lowered thyroid hormone entry into the nucleus of hepatocytes, neurons, and fibroblasts. This clinical study follows from previous work suggesting that carnitine is a naturally occurring inhibitor of thyroid hormone nuclear uptake.¹⁹³ Therefore, high levels of carnitine in a hypothyroid patient could result in exacerbation of symptoms.

Resistance to Thyroid Hormone

Beyond the production of T_4 and its conversion to T_3 is the transport of the hormone and its ultimate activity as a transcription activator at the nuclear receptor site.¹⁹⁴ Resistance to this process at the subsequent steps can result in what has been called "thyroid resistance." A number of genetic polymorphisms are associated with thyroid resistance. Therapy for thyroid resistance can be compared to therapy for insulin resistance, which is often treated clinically by administering high doses of insulin to overcome the resistance. Similarly, high levels of thyroid hormone replacement have been used clinically to overcome thyroid receptor hormone insensitivity.¹⁹⁵

Animals with mutations in the thyroid hormone receptor genes exhibit impaired growth and resistance to thyroid hormone activity.¹⁹⁶ This resistance could be seen as “euthyroid sick syndrome,” in which the individual has reasonably normal levels of T_4 , T_3 , and TSH but exhibits symptoms associated with thyroid dysfunction.¹⁹⁷ Recognizing the existence of multiple forms of thyroid hormone receptors that can produce multiple phenotypes based upon the environment of the individual has improved the understanding of ways to manage some forms of thyroid dysfunction. Variations may exist in all areas of thyroid metabolism, including polymorphisms in the deiodinase enzymes as well as the alterations of T_3 activities.^{198,199}

Heterodimerization

Thyroid hormone receptors are part of the nuclear steroid hormone family of receptors, which also includes peroxisome proliferated activated receptors (PPARs) and the retinoic acid receptors. One recent development in this field is the recognition that thyroid hormones must properly bind to the nuclear hormone receptor to be active at the genomic level, and this binding may depend upon what is called “heterodimerization” with other receptors.²⁰⁰ Alterations in the genotype of these receptor proteins can result in significantly different DNA binding activities in different individuals.²⁰¹ A number of studies have attempted to identify how the thyroid receptor interacts with other receptors to induce specific effects on gene expression.^{202,203,204,205,206,207}

Effect of Vitamin A on Thyroid Function

As discussed in the previous essay, a number of environmental and nutritional agents (triggers) can modify orphan nuclear receptors. These modifications have the potential to alter the effect of T_3 at the gene transcription level.^{208,209} One such modifiable factor is vitamin A intake and its effect on retinoic acid synthesis and activation of the retinoic acid receptor.^{210,211} (Another that we won't explore here is insulin sensitivity and its relationship to the activity of the PPAR receptor.²¹²) Studies have found PPAR agonists have thyromimetic effects,²¹³ suggesting that substances like omega-3 fatty acids, including EPA and DHA as well as conjugated linoleic acid (CLA), may play roles in thyroid function.

Chronic illnesses associated with aging may adversely influence thyroid function. In addition, it has been shown in animals that gene expression changes with aging result in decreased abundance of the retinoic acid and T_3 nuclear receptors.²¹⁴ The binding of T_3 to its nuclear receptor is retinoic acid-dependent, suggesting that factors that lower retinoic acid levels may result in lower thyroid hormone effect at the nuclear receptor.

Factors that either produce vitamin A (retinol) insufficiency or prevent the conversion of vitamin A to retinoic acid may result in reduced thyroid nuclear signaling.^{215,216,217} One source of vitamin A is through conversion of beta-carotene to an active form of vitamin A in the intestinal mucosa.²¹⁸ Homocysteine elevation has also been shown to inhibit the conversion of retinol to retinoic acid in cell cultures.²¹⁹ Excess alcohol consumption may also reduce the production of retinoic acid.²²⁰

The increasing understanding that specific nutrients influence hormone receptor gene interactions that then influence disease expression is a remarkable new chapter in understanding the etiology of chronic disease.²²¹ Vitamins A and D have been identified as important “prohormones” that help regulate these gene expression pathways shared with T_3 .

It seems remarkable that specific dietary fats and vitamin A could have such dramatic impact on thyroid hormone activity but, as this story of nuclear receptor regulatory factors emerges, it appears clear that these relationships do exist.²²² This is an extraordinarily complex story because multiple polymorphisms are related to multiple steps in this process. We cannot simply say, therefore, that all people with thyroid hormone resistance are suffering from vitamin A insufficiencies.

The Mitochondrial Connection to Thyroid Hormone Activity

Increasing evidence in the literature indicates that T_3 has a direct impact on mitochondrial function. It is interesting to note that diiodo-L-thyronine (T_2) seems to have binding sites in the mitochondria.²²³ T_2 is generated from T_3 and rT_3 . Recent data suggest T_2 can stimulate mitochondrial respiration and, therefore, thyroid hormone status can influence mitochondrial function.^{224,225}

In essence, we are beginning to recognize that thyroid hormones play a role, through receptor activities, in mitochondrial function. Conditions that either prevent the proper formation of T_3 , or increase the formation of rT_3 , or inhibit the appropriate binding of T_3 to its nuclear receptor, may result in symptoms of thyroid insufficiency. Increased levels of rT_3 are also associated with increased autoantibodies in the thyroid gland. A patient may start developing a general autoimmunity to his or her endocrine function, associated with increased senescence and a range of age-related chronic illnesses.^{226,227} Proper metabolism of T_4 to T_3 and, subsequently, T_3 to T_2 is critical in controlling the communication to the mitochondria and their subsequent energy reduction.^{228,229} Through this process, thyroid hormones can exert both a genomic expression effect on cellular physiology and a rapid response effect that does not require protein synthesis on mitochondrial energy production.²³⁰ Deficiencies in the regulation of this thyroid-modulated mitochondrial pathway can also have adverse impact on growth hormone synthesis and regulation of other anabolic functions.

In essence, this two-step process associated with metabolic regulation by thyroid hormones may account for many of the features associated with healthy or unhealthy aging. Thyroid hormones, particularly T_3 , have a profound effect on cellular respiration and mitochondrial function, both indirectly through activity of the nuclear receptor family on gene transcription, and directly on the impact of T_3 on the mitochondrial respiratory enzymes.^{231,232,233,234}

Clinical Effects of Thyroid Imbalance

The clinical effects of thyroid imbalance or dysfunction may be observed as poor thermogenic responsiveness and a tendency to gain weight associated with insulin resistance, hypercortisolemia, and under-conversion hypothyroidism. This clinical picture is further characterized by elevated postprandial insulin, decreased level of T_3 with increased rT_3 , low axillary body temperature on waking, elevated triglycerides with a reduced HDL level, and a tendency to gain weight as visceral adipose tissue with an increase in waist-to-hip ratio.

T_3 is important for activating thermogenesis in adipocyte cells.²³⁵ It appears to accomplish this thermogenic effect by activating what are called uncoupling proteins (UCPs) in various tissues.^{236,237} The proper ratio of T_3 to rT_3 is critically important in expressing mitochondrial

UCPs. Patients with energy production problems, poor thermogenesis, and symptoms of functional hypothyroidism may be suffering from either underproduction of T_3 or overproduction of rT_3 , both of which are often found in states of overactivation of the HPT axis.

Once again, this calls for the application of the functional medicine model that ties together the activity of the adrenal axis with that of the thyroid axis. If a patient is suffering from hyperactivity of adrenocortical function, this needs to be stabilized while also focusing on appropriate T_3 production and sensitivity.

Thyroid Autoantibodies

One contributor to lack of proper T_3 production is higher titers of antithyroidal antibodies that impair proper thyroid hormone metabolism and sensitivity. In the extreme case, one might think of Hashimoto's disease as the diagnosis of autoimmune thyroiditis. Well before that disease sets in, however, there are states of functional impairment of thyroid activity²³⁸ that result from marginally elevated antithyroid antibodies against many of the thyroid proteins.^{239,240}

Down syndrome and thyroid abnormalities. One clinical condition in which elevated levels of antithyroid antibodies are quite common is in Down syndrome. Children with Down syndrome are often found to have thyroid abnormalities.²⁴¹ One study has found an association between low serum levels of selenium and thyroid hypofunction in Down's patients.²⁴² Down syndrome children appear to develop thyroid autoantibodies as they age past eight years.^{243,244} The literature suggests that thyroid autoimmunity and resulting thyroid dysfunction in children with Down syndrome may be one of the principal determinants of some of the functional problems they encounter as they grow older. Researchers have recently observed an association between the presence of thyroid autoantibodies and gastrointestinal abnormalities in Down syndrome infants with congenital hypothyroidism.²⁴⁵

Gut-associated lymphoid tissue (GALT) and thyroid function. It may at first seem incongruous to suggest that the gut is somehow connected to the thyroid gland, but we have recently learned that the gut-associated lymphoid tissue (GALT) plays a role in priming the rest of the body's immune system. Therefore, when the gut encounters antigens for which antibodies are produced, an impact may occur on inflammatory mediators elsewhere in the body. An association between

autoimmune thyroid disease and celiac disease has been noted in a study that reports the presence of anti-endomysium antibodies was ten-fold higher than expected in patients with celiac disease who had autoimmune thyroid disorders, suggesting the two share common immunopathogenic mechanisms.²⁴⁶

Managing thyroid autoantibodies with gluten-free diet. A case report in 1999 described a 23-year-old woman with a diagnosis of hypothyroidism due to Hashimoto's thyroiditis and autoimmune Addison's disease, who was found to have elevated anti-endomysium antibodies. Over a three-month period on a gluten-free diet, this woman showed remarkable clinical improvement in both her gastrointestinal-related symptoms and, more importantly, in her thyroid function. She required progressively less thyroid and adrenal replacement therapy. After six months, her endomysium antibodies became negative, her antithyroidal antibody titer decreased significantly, and thyroid medication was discontinued.²⁴⁷ This case points out the potential impact of a hypoallergenic diet on thyroid function in the reduction of antithyroidal antibodies. Gluten sensitivity is being reported with increasing frequency in numerous conditions (discussed further in Chapter 31); a 2002 review of diagnostic tests in IBS concluded, for example, that the only screening test likely to be useful in that patient population was the routine performance of serological testing for celiac disease.²⁴⁸

The same theme is mirrored in a number of other studies. An article in the *American Journal of Gastroenterology* described the importance of gluten in the induction of endocrine autoantibodies and organ system dysfunction in adolescent celiac patients.²⁴⁹ Another study evaluated 48 patients with celiac disease and thyroid dysfunction. It found that those individuals who carried the DQ131*0502 genotype had a strong risk of thyroid autoantibodies as a consequence of gluten sensitivity.²⁵⁰ A *Journal of Pediatrics* article reported that gluten-dependent diabetes and thyroid-related autoantibodies found in patients with celiac disease were abolished after a gluten-free diet was followed.²⁵¹ And a study published in the *Canadian Journal of Gastroenterology* described a 66-year-old woman with dermatitis herpetiformis and biopsy-defined celiac disease who developed a thyroid mass that later proved to be a T cell lymphoma.²⁵²

The congenital gastrointestinal abnormalities in Down syndrome suggest a potential connection between gluten sensitivity and autoantibodies to the thyroid gland. According to a 2001 study describing the immune-endocrine status in celiac disease in children with Down syndrome, "Dietary antigens may represent a continuous stimulus for the immune system in this syndrome and interfere with normal immune responses. Altered intestinal absorption of nutrients may in turn affect endocrine functions, brain development, and cognitive performances."²⁵³

Similarly, a study in the *American Journal of Gastroenterology* (also in 2001) reported that there is a high prevalence of thyroid disorders in untreated adult celiac disease patients and that gluten withdrawal through dietary avoidance may single-handedly reverse this abnormality.²⁵⁴

It is obvious from this discussion that a low-antigen dietary approach is desirable in patients with thyroid autoantibodies and altered thyroid function. Gluten is an important dietary variable that can modify thyroid hormone activity. Since rice has low antigenicity and is gluten-free, a rice-based diet may be desirable in these patients.

Inflammatory cytokines and thyroid function. Psychosocial, chemical, and physical stressors can also increase the level of inflammatory mediators (the cytokines) that alter thyroid hormone function and activity. One study, which looked at military cadets involved in special forces training, found the extensive stress of this training resulted in elevated cortisol, reduced testosterone, and increased TSH, but significant reductions in T₃.²⁵⁵ This study also found evidence of elevated inflammatory cytokines and increased gastrointestinal permeability as a consequence of these inflammatory factors.

Treating patients with proinflammatory cytokines such as interleukin-2, may lead to hypothyroidism as a consequence of the production of antithyroidal antibodies in cancer patients.²⁵⁶ A study evaluating the cytokine levels in hypothyroid patients contrasted to age-matched, sex-matched euthyroid controls, found a significant elevation in IL-2 in the hypothyroid patients, once again potentially linking activation of the inflammatory system with the production of autoantibodies to the thyroid.²⁵⁷

A study in 2000 indicated that hypothyroid patients with autoimmune thyroiditis have a disruption in the normal balance between the Th1 and Th2 cytokines.²⁵⁸ Patients with subclinical hypothyroidism (SH), irrespective of gender, have higher serum hs-CRP, insulin, total and LDL cholesterol levels than healthy subjects. The conclusion drawn from this study was that an elevated hs-CRP level (and therefore low-grade inflammation) may be associated with fasting hyperinsulinemia before insulin resistance becomes evident in patients with SH.²⁵⁹ Reduction in inflammatory cytokines can be achieved through a variety of dietary, lifestyle, and environmental factors, including lowering physical and emotional stressors, reducing antigens and toxin exposure and improving nutritional factors associated with the support of balanced immune function.

Vitamin D. One nutrient that is critically important for establishing immune balance and preventing the production of autoantibodies is vitamin D. Vitamin D suppresses the development of autoimmune diseases, such as arthritis and multiple sclerosis, in experimental animal models.²⁶⁰ Vitamin D insufficiency increases the severity of experimental autoimmune encephalitis. It is interesting to speculate that the role of vitamin D in the immune system may have a downstream effect on thyroid hormone activity.

Vitamin D is considered a prohormone that is converted by activity at the liver and kidney into 1,25-dihydroxy vitamin D3, a hormone with immunomodulatory properties. 1,25-dihydroxy D3 has antiproliferative, differentiating, and immunosuppressive activities.²⁶¹ Animals fed vitamin D-insufficient diets had profound increases in serum levels of interleukin-2,²⁶² which, as noted above, may be associated with thyroid autoantibodies. Vitamin D appears to work with other nutritional factors to help regulate immune sensitivity and to protect against development of autoantibodies.

Zinc. Another nutrient that is beneficial in establishing hormone balance is zinc. Plasma zinc levels are often compromised in Down syndrome children, and zinc therapy can reduce thyroidal antibodies and improve thyroid function.²⁶³ Research suggests that zinc supplementation affects the metabolism of thyroid hormones and reduces antithyroidal antibodies in Down syndrome children.²⁶⁴ Supplementation with zinc sulfate improves thyroid function in Down syndrome children, and reduces the incidence of subclinical hypothyroidism.²⁶⁵

In a clinical trial with disabled patients who displayed compromised thyroid parameters, supplementation with 4 to 10 mg of zinc sulfate per kg body weight (50–100 mg of elemental zinc) resulted in increased levels of serum free T₃, reduced levels of rT₃ and normalized TSH levels.²⁶⁶ A study of older-aged individuals found that the low T₃-to-T₄ ratio was related to impaired zinc and/or selenium status.²⁶⁷ This follows closely the previous discussions of the role of both selenium and zinc in promoting proper thyroid function, selenium through its deiodination, the activity of thyroid hormones, and zinc by its role as a cofactor for the thyroid receptor.

Xenobiotics and their Relationship to Thyroid Function

Other environmental factors are known to influence antithyroidal antibodies and thyroid hormone metabolism. The developing brain of the fetus has significant vulnerability to thyroid abnormalities caused by environmental insults *in utero*.²⁶⁸ In both fetal and neonatal stages, the nervous system is vulnerable to the adverse effects of toxic substances on thyroid gland function or activities.

Porterfield pointed out that a number of the environmental toxins to which we are now exposed, such as dioxins and PCBs, have abnormal effects on thyroid function that can result in neurological impairment. These compounds appear to act as agonists or antagonists for receptors of the thyroid steroid retinoic acid super-family of nuclear receptors.²⁶⁹ The resulting “twisted molecules” serve as endocrine disruptors that have an adverse influence on the function of the thyroid axis. Organochlorine compounds interact with thyroid-binding globulin and disrupt thyroid hormone metabolism.²⁷⁰

Citizens of a small town in Colombia had a significant prevalence of autoimmune thyroiditis, which was traced back to the contamination of drinking water with phenolic chemicals. Those chemicals adversely influenced the immune system, resulting in production of antithyroidal antibodies.^{271,272} When the water supply was purified, the prevalence of autoimmune thyroiditis was significantly reduced in the community.

A number of mechanisms of chemical injury to the thyroid gland have been identified. They include inhibition of the iodine-trapping mechanism, blockage of organic binding of iodine, coupling of iodothyronines

to thyroxine, and inhibition of thyroid hormone activity, as well as the production of thyroid antibodies.²⁷³ Clinically, this may be seen as resistance to thyroid hormones, and the person may experience refractory response to hormone replacement therapy.²⁷⁴ The suggestion has been made that exposure to even modest levels of PCBs in the food supply might result in the production of mild hypothyroidism.²⁷⁵ Sensitivity to these chemicals may be most profound in the thyroid function of infants and children; however, it could have impact on thyroid function in adults as well.²⁷⁶

Approaches to Managing HPT Axis Imbalances

Our understanding of thyroid function, its relationship to hypothalamic and pituitary function, and the interrelationship with aspects of adrenal and immune function, is developing at the clinical, cellular, and molecular biological levels. In a paper in *The New England Journal of Medicine*,²⁷⁷ Klein and Ojamaa describe the relationship of thyroid hormones to the cardiovascular system, and the pleiotropic effects of thyroid hormone across a wide range of functions. All of these effects are triggered through the binding of T_3 to the thyroid hormone response elements in the genome and the inducing of transcription and translation of proteins that alter the phenotype, such as that of the cardiac myocyte. This is just one of a number of papers describing the role of the hypothalamus/pituitary/thyroid axis across a wide range of organs and organ systems, and clarifying how these functional attributes relate to chronic disease in aging individuals.

Taking into account many aspects of this extended essay on cellular messaging as it relates to thyroid function, one can develop a checklist of criteria for clinicians in evaluating patients with imbalances in the function of their hypothalamus/pituitary/thyroid axis:

1. *Provide adequate precursors for the formation of thyroxine (T_4).* Iodide is a limiting nutrient in many individuals for the production of thyroxine. Adequate levels of organic iodide, which can come from seaweed, are important in thyroxine production.^{278,279} Supplementation with tyrosine does not appear to have a beneficial effect on elevating thyroid hormones. However, adequate dietary protein intake is important in establishing proper protein-calorie nutrition.
2. *Reduce antithyroidal antibodies.* A variety of food antigens can induce antibodies that cross-react

with the thyroid gland. The relationship between celiac disease and autoimmune hypothyroidism has been discussed. A food elimination diet utilizing gluten-free grains and possible elimination of dairy proteins that contain casein, the predominant milk protein, may be desirable in patients with hypothyroidism of unexplained origin. It has also been suggested that environmental xenobiotics may play a role in inducing autoimmune thyroiditis and thyroid dysfunction.

3. *Eliminate exposure to xenobiotics.* One clinical approach for patients with borderline hypothyroidism would be to implement a detoxification program, focused first on eliminating the sources of toxin exposure, and then on nutritional support of phase I and phase II detoxification reactions and adequate levels of vitamin D to support balanced reactions in the immune system. The purpose of this approach would be to nutritionally support hepatic and intestinal detoxification systems, reduce body burden of stored toxins, and decrease antithyroidal antibodies produced as a consequence of "cross-talk" between the immune system with exogenous toxins.
4. *Improve the conversion of thyroxine to tri-iodothyronine (T_4 to T_3).* Nutritional agents that support proper intracellular deiodination by the Type 1 5'deiodinase enzyme include selenium as selenium methionine. Adrenal support also reduces excess production of cortisol or enhances cortisol detoxification.
5. *Improve T_3 receptor binding.* The role that T_3 appears to play is through its nuclear receptor super-family and its effects on gene transcription. T_3 also has direct effects through receptors found in the mitochondria that engage in controlling oxidative phosphorylation and energy production. These receptors interact with vitamin A and PPAR agonists like CLA, EPA, and DHA. Intake of adequate vitamin A in a preformed state, along with adequate levels of omega-3 fatty acids, plays an important role in this interaction. EPA and DHA increase thermogenesis in animals and selectively improve gene transcription related to thyroid function. Vitamin A is converted into all-*trans* retinoic acid through a series of metabolic steps. It then regulates the retinoic acid receptor that interacts with the thyroid receptors, and may help to improve thyroid hormone activity. Carnosic acid, which is one of the principal constituents in rose-

mary concentrate, was found to potentiate the effects of vitamin D and retinoic acid on monocyte differentiation.²⁸⁰ Carnosic acid is a powerful antioxidant.²⁸¹ Zinc as zinc clycinate, has also been shown to be important in promoting proper thyroid function, by its role as a cofactor for the thyroid receptor.

6. *Enhance T_3 influence on mitochondrial bioenergetics.* As explained earlier, a number of important nutritional relationships improve thyroid hormone's effect on the mitochondria. Selenium supplementation in animals can improve the production of T_3 and lower autoantibodies to thyroid hormones, while improving energy production. Supplementation with selenium methionine results in improved deiodination of T_4 , which may improve ATP formation by supporting improved mitochondrial activity.²⁸²

Supplementation and Thyroid Function

Research described in a paper in the *Journal of Endocrinology* in 1998²⁸³ evaluated the antigoirogenic effects of a combined supplement of vitamin E, vitamin A as beta-carotene, and vitamin C in aging animals. Results of this study suggested these vitamins, vitamin E in particular, modulate the regulatory cascades involved in the control of thyroid function.

In a placebo-controlled trial in 2001, thyroid function responded to selenium supplementation (selenium methionine), particularly in individuals with posttraumatic or stress-induced alterations of the thyroid axis. Subjects in this human clinical trial were given 500 mg of selenium daily with or without 150 mg of alpha-tocopherol and 13 mg of zinc. Supplementation resulted in modest changes in thyroid hormones with an increase in T_3 and a reduction in rT_3 .²⁸⁴

This observation is consistent with the recognition that selenium, vitamin E, and vitamin C play a role in the antioxidant-sensitive T_3 effects on induced mitochondrial function.²⁸⁵ Vitamin E has a protective effect against the lead-induced deterioration of 5'deiodinase activity.²⁸⁶ It might, therefore, influence thyroid function positively by several mechanisms. In a clinical trial assessing the safety of high-dose, short-term supplementation of vitamin E in healthy older adults, Meydani and Blumberg reported that a daily supplement of 800 mg of vitamin E resulted in a reduction in inflammatory cytokines, but had no adverse effect on thyroid function.²⁸⁷

Another study, in chickens, also seemed to support the positive influence of antioxidants on thyroid activity at the mitochondrial level. Chickens supplemented with vitamin C and treated with the antithyroidal drug propylthiouracil, had normal thyroid function. This study suggests vitamin C improves thyroid function in animals with hypothyroidism experimentally induced through toxic exposure.²⁸⁸

Similarly, other published work suggests an interrelationship between thyroid hormones and vitamin A and zinc nutritional status. One such report suggests a causal relationship between the pathogenesis of deranged vitamin A metabolism and a low T_3 syndrome, either by interfering with T_4 entry into the tissues or by directly affecting the enzymatic conversion of T_4 to T_3 .²⁸⁹ Subjects in this study were stable patients with hepatic or gastrointestinal disorders that modified the absorption and metabolism of vitamin A and zinc. Animal studies indicate aging decreases the vitamin A and T_3 nuclear expression, suggesting that exogenous or supplemental vitamin A may be important for increasing retinoic acid levels in order to modulate this decreased expression.²⁹⁰ A companion study, in which supplemental vitamin A was able to increase activity at the T_3 nuclear receptor in the brain of aging animals, produced the same result.²⁹¹ Other animal studies have shown nicotinamide modulates expression of thyrotropin.²⁹²

Natural Therapies before Pharmacology in Thyroid Dysfunction

Thyroid hormones have both gene expression and non-genomic effects on cellular metabolism. Many of these effects are clearly related to nutritional status and integrate into a larger picture that also involves psychosocial and environmental modulators that influence the HPT axis. These signaling pathways control multiple functions in the individual, translating environmental signals into physiological function. For example, cell signaling processes initiated by thyroid hormones are intertwined with the vitamin A and D signaling pathways.^{293,294} Taken together, the results from limited human clinical trials, animal studies, *in vitro* work, and epidemiological evidence may strongly indicate but do not conclusively prove the hypothesis that functional modifications will serve as therapeutic interventions for improving outcome in patients with chronic thyroid dysfunctions.

Clearly, the proof of the concept is in the clinical outcome of the patient who has been evaluated and managed by a functional medicine approach. In the absence of clinical intervention studies assessing the effectiveness of this complex algorithm for the management of thyroid-related dysfunctions, the clinician must rely on an understanding of complex mechanisms, their disruptors and supporters, and on empirical clinical evidence. At worst, the effects of the nutrients listed at the levels suggested should produce no untoward effects, and there is a reasonable amount of science to indicate they should be helpful.

Fortunately, a growing evidence base provides support for this empirical approach. To summarize, we are suggesting the following steps: 1) provide adequate precursors for thyroxine formation; 2) reduce antithyroidal antibodies by lowering immune potential, improving the conversion of T_4 to T_3 , and improving receptor binding of T_3 ; and 3) activate mitochondrial bioenergetics through balanced thyroid function. All of this may be accomplished in many patients by modification of nutrition, lifestyle, and environment.

In this review of thyroid function, we have examined the production of thyroid messenger substances, the transport of thyroid messenger substance, the issues of tissue sensitivity to the message, the intracellular response to thyroid hormones, and detoxification and excretion of messenger substances. We have delved deeply into thyroid function as an example of how functional endocrinology develops a more complex understanding of inter- and intracellular communication and cross-talk. The last essay in this chapter again addresses thyroid function, with a focus on specific clinical interventions for improving patient outcomes.

We will now attend to the adrenal hormones (focusing on DHEA HRT) and the HPA axis, growth hormone dynamics, and insulin-like growth factors, using these specific areas of investigation to further elaborate the evolving model of functional neuroendocrine-immunology.

Stress, Adrenal Function, and The HPA Axis, with a Focus on DHEA HRT

One of the environmental modulators of neuroendocrine function is physical or psychosocial stress. Interaction between the neuroendocrine system and

the external environment often occurs through the senses, creating a substantial impact on the hypothalamus/pituitary/adrenal (HPA) axis.

Long-term, unremitting stress results in loss of adrenal gland reserve related to the reduced production of stress hormones like cortisol and epinephrine. Under stress, the human adrenal cortex secretes not only the essential hormones cortisol and aldosterone, but also dehydroepiandrosterone (DHEA) and large amounts of dehydroepiandrosterone sulfate (DHEA-S). The serum concentration of DHEA-S is 20 times that of serum cortisol, whereas the concentration of free DHEA is 1/20th that of cortisol. The high concentration of DHEA-S reflects its high rate of secretion by the adrenal cortex and its low rate of metabolic clearance. DHEA is produced from DHEA-S in the zona reticularis of the adrenal gland and in the liver by a sulfotransferase. Many organs that are targets of androgens and estrogens also convert DHEA-S back to DHEA; the same organs can then biotransform it into an active androgen like testosterone or estrogens.^{295,296}

In normal individuals, serum concentrations of DHEA and its sulfate are highest at age 30. After age 30, concentrations of both gradually decrease. By age 70 or 80, the values are about 20% of peak values in men and 30% of peak values in women. This decrease has led to the suggestion that DHEA might be a marker compound for the effects of stress on endocrine function, and the postulate that supplementation with DHEA might help support proper endocrine function in individuals with low values of DHEA-S and DHEA.

Since the ovaries do not secrete DHEA and the testes secrete only small amounts, adults with primary or secondary adrenal insufficiencies often have very low concentrations of DHEA and its sulfate and low levels of androgens derived from DHEA.²⁹⁷ In a study of men and women with severe hypopituitarism, administration of a single oral dose of 50 mg of DHEA transiently raised serum concentrations of DHEA, its sulfate, and androstenedione (known to be a precursor of both testosterone and estrogen) into the normal range for young adults.²⁹⁸ It also raised the serum concentrations of estrogens and active androgens (testosterone and dihydrotestosterone), but only in the lower end of the normal range for young women (based on normals for the early follicular phase of the menstrual cycle).

Evaluating DHEA Replacement: A Model for Evaluating Pros/Cons of HRT

In 1999, Arlt et al. evaluated the psychological and biochemical effects of DHEA replacement in women with adrenal insufficiency.²⁹⁹ They administered DHEA orally in a dose of 50 mg per day or placebo for four months and evaluated the effects on well-being and sexuality, as well as serum hormone values. Some of the women had primary or secondary hypogonadism, and some were postmenopausal; if they were taking estrogen-progestin replacement therapy for these concerns, they were counseled to continue the oral hormone therapy during the study. After treatment, serum DHEA, DHEA-S, and androstenedione concentrations increased from initial low values to normal, and serum testosterone and dihydrotestosterone concentrations rose to the lower limit of the normal range in the women. Serum estrogen concentrations did not change significantly, possibly because of a small increase obscured by the estrogen replacement therapy used by some of the participants. Evaluation of psychological factors by questionnaire found positive effects of DHEA on depression, anxiety, general well-being, and the physical aspects of sexuality. There was also a small but significant rise in serum insulin-like growth factor-1 concentrations (a mediator of some effects of growth hormone in the liver), and a small decrease in total and low-density lipoprotein cholesterol concentrations.

One problem with DHEA is that it serves as a precursor to androgens. Because DHEA can stimulate the synthesis of testosterone, it should be administered with caution to women who may be hyperandrogenic. Excessive use can cause acne, unwanted hair growth, or adverse influence on the menstrual cycle in women. With the passage of the U.S. Dietary Supplement Health and Education Act of 1994 (DSHEA), DHEA has become widely available, and a growing market has developed for this so-called “fountain of youth.” It is often available through direct mail outlets with no recommendation for hormone or endocrine balance evaluation before administration. Promoters have claimed DHEA is a “super hormone” that can help overcome obesity; build muscle mass; prevent cancer, heart disease, and type 2 diabetes; slow aging; prevent or slow the progression of Alzheimer’s and Parkinson’s diseases; boost libido; strengthen the immune system; and help treat systemic lupus erythematosus.

Unfortunately, many of these claims are as yet unsubstantiated,³⁰⁰ and none of them should be used to promote unmonitored use of powerful hormones without trained clinical guidance. Very few randomized clinical trials have been performed on long-term effects of DHEA in humans for these conditions. DHEA metabolism in animals is very different from that in humans. For example, primates show a higher level of adrenal steroidogenesis than do humans. Differences in metabolism of DHEA and other steroids have also been noted between humans and many animal species. Extrapolation of encouraging research results of DHEA administration studies in animals for use in humans requires careful ongoing evaluation.

The results to date suggest it may be justified to prescribe a daily dose of 5 to 20 mg of DHEA for patients with defined adrenal insufficiency, whose sexuality and well-being are subnormal, **provided** they are monitored for breast or prostate cancer and managed by a competent clinician. It is very important to precede the administration of DHEA with salivary or serum tests for DHEA and DHEA-S, as well as testosterone and estradiol. A baseline hormone analysis is critical to establish the overall influence of DHEA on neuroendocrine balance. It is inappropriate to administer DHEA based on clinical symptoms alone. Other possible indications for replacement with DHEA include depression associated with low hormone levels and, since estrogen can be increased by DHEA, possibly postmenopausal osteoporosis.³⁰¹ In a recent placebo-controlled trial involving patients with major depression, treatment with DHEA (maximum dose of 90 mg per day) resulted in significant improvement in the Hamilton Depression Rating Score as compared to placebo.³⁰²

Evaluating Growth Hormone Function

Growth hormone (GH), an endogenous growth factor produced by the anterior pituitary gland, is involved primarily in skeletal and soft-tissue growth.³⁰³ It also participates in numerous metabolic feedback loops, and has been found to be anabolic in skeletal muscle tissue,³⁰⁴ lipolytic in peripheral fat stores, and induces the breakdown of glycogen in the liver.³⁰⁵ Clinicians have used these effects to treat growth-deficient patients,³⁰⁶ to attenuate catabolism in the aged and critically ill, and in trauma and burn patients.

As we grow older, we experience a decrease in lean body mass and bone density, and a reduction in the size of the internal organs, suggesting loss of organ reserve. These symptoms may be associated with loss of GH. The healthy young man between age 20 and 30 secretes between 0.5 and 1.0 mg of GH each day. Secretion declines by about 14% per decade. In some elderly people, GH production cannot be detected at all.³⁰⁷

GH is a peptide hormone of approximately 22 kD in molecular weight with 191 amino acids, having two disulfide bridges joining cysteines. Base sequence analysis reveals that growth hormone is homologous to both prolactin and placental lactogen. GH receptors are found in a wide variety of tissues, including muscle, bone, liver, heart, and lymphoid organs. GH induces the secretion of another hormone made by the liver called somatomedin C, or insulin-like growth factor (IGF-1). It appears that many, though not all, effects of GH are actually mediated by IGF-1.³⁰⁸ Although GH concentration follows a diurnal rhythm, IGF-1 concentrations do not fluctuate in the course of a day. Consequently, IGF-1 concentration is often taken as a diagnostic indicator of GH output.

GH and IGF-1 decline with age. If GH output declines with age, it might be expected that IGF-1 concentrations would also decline. In fact, there is a close relationship between the 24-hour average output of GH and the concentration of IGF-1 in the bloodstream. In the decades between ages 40 and 80, the average IGF-1 concentration falls from 800 units per liter to 570, then to 410 units per liter and 320, respectively.³⁰⁹ The reduced concentration reflects declining GH output rather than a diminished liver responsiveness to GH because injection of GH, even in elderly people, results in a rapid rise in IGF-1. Therefore, the decline of IGF-1 concentration appears to be the result of events associated with aging that can be traced back to a decline in GH secretion, which results from a decrease in the hypothalamic output of GH-releasing hormone (GHRH).

In 1990, two independent studies tested GH injections in the elderly. Both lasted six months and showed positive metabolic effects.³¹⁰ In one study involving 16 healthy men and women over age 60, IGF-1 levels rose in direct proportion to the amount of GH used. In a second study, 21 healthy men between 61 and 81 years of age also showed an increase in IGF-1 after GH injections. However, when treatment was extended in these men for a year, significant adverse side effects were noted with the GH therapy. Ten instances of carpal tunnel syndrome

(24%) and two examples (9%) of gynecomastia were reported. Adverse side effects were generally limited to subjects whose IGF-1 was brought to the higher end of the normal IGF-1 range. This study suggests that for GH therapy to be effective in the elderly, great care should be taken to use a dose that brings plasma levels of IGF-1 to no higher than the 500–1000 units-per-liter range.

Growth Hormone Replacement Considerations

GH deficiency is associated with increased risk of cardiovascular mortality, and it has been suggested this is a consequence of altered lipid dynamics and arterial function related to GH deficiency.³¹¹ GH deficiency is associated with abnormalities in plasma lipoproteins, including increased LDL and plasma triglycerides, and low HDL levels. Several studies have shown that GH replacement therapy in individuals who are GH deficient is able to lower plasma total and LDL cholesterol, as well as increase HDL.^{312,313}

In 24 GH-deficient adults, GH replacement therapy was shown to elevate the activity of plasma lecithin-cholesterol acyltransferase. In this study, GH deficiency was defined as peak serum GH levels in response to insulin-induced hypoglycemia (a venous blood glucose less than or equal to 2.2 mmol per liter in the presence of hypoglycemic symptoms). Regular insulin was intravenously administered in a dose of 0.15 to 0.20 units per kilogram body weight to induce the hypoglycemia, and growth hormone levels were measured at the low blood glucose nadir. It is important to point out that these subjects were adults with demonstrated GH deficiency and, therefore, the results may not apply to older individuals with no demonstrable GH deficiency.

GH administration contributes to insulin resistance and may consequently contribute to the development of type 2 diabetes in some individuals. In a recent study, GH-deficient children who received GH therapy had no increase in type 1 diabetes, but experienced a six-fold increase in type 2 diabetes.³¹⁴ In spite of the effect of GH on insulin resistance, GH supplementation has been shown, in individuals who are GH deficient, to reduce the risk of cardiovascular disease and possibly improve well-being.³¹⁵

These studies make a very important point about the therapeutic use of GH: it should generally be considered only for adults with established severe GH deficiency. GH administration to an individual in the normal GH range may result in adverse side effects, including type

2 diabetes and musculoskeletal problems.³¹⁶ Cardiovascular risk reduction can be achieved with nutritional and lifestyle strategies; if those efforts are unsuccessful, pharmaceutical approaches are available. The effect of GH on the structure of body fat, muscle, and bone can be addressed by other means as well, including optimum hormone replacement therapy and a structured exercise and lifestyle program.³¹⁷

Stimulating GH Release

We know exercise induces the neuroendocrine release of GH, although the mechanism by which it does so remains unclear. A study in 2000 found the GH levels of exercising athletes were highest 30 minutes after exercise and could be elevated even with modest workloads.³¹⁸ The study data indicate that under strenuous exercise conditions, endogenous GH-releasing hormone activity causes a further increase of GH release. A GH-releasing protein-2-mediated mechanism in central neuroendocrine regulation seems to act as a booster, possibly by stimulating the effects of GH-releasing hormone, indicating a graded effect of exercise on GH activities.

Because GH secretion is controlled by both GH-releasing hormone and GH-releasing peptides as secretagogues, new therapeutic approaches focus on stimulating the secretion and balance of GH. Researchers have discovered small GH-releasing peptides that seem to work by an entirely new signaling pathway.³¹⁹ This pathway does not depend on releasing factors of hypothalamic origin. It does not involve receptors of GH-releasing hormone or a cyclic AMP-mediated signaling pathway, and its signaling potential does not diminish with age. The signaling pathway for GH-releasing peptides is activated through small 5-amino acid peptides that seem to induce GH secretion.

GH and IGF-1 Supplementation

Ongoing clinical trials are evaluating the administration of recombinant IGF-1. Although GH is diabetogenic and causes water retention, IGF-1 does not have these effects. However, there are some countervailing concerns about IGF-1. It is a potent stimulator of cell replication and thus may be associated with the induction of cancer. IGF-1 suppresses apoptosis, and most tumors express IGF-1 receptors. High IGF-1 levels in males are associated with an increased risk of prostate cancer.³²⁰ As a whole, the clinical outcomes of supplementation with

GH, IGF-1, or GH secretagogues are as yet unclear. Whatever strategy is used, levels of IGF-1 and GH should be measured prior to administration of any exogenous growth factors. Evaluating IGF-1 levels appears to be critically important in defining the hormonal milieu related to growth factors. IGF-1 levels in individuals younger than age 40 range from 800-1000 units per liter. In 60-year-olds, those levels are about 400 units per liter. It is not clear whether elevated levels of IGF-1 in older individuals are associated with significantly increased risk of prostate, breast, or other cancers. The decision to increase IGF-1 levels by administering GH should be approached with caution. The first steps in implementing a GH support strategy should be exercise, insulin balance, and DHEA support.

Melatonin and the Menopausal Female Neuroendocrine System

The onset of menopause, characterized by the cessation of menstruation, signals not only the end of fertility, but also the beginning of a multitude of alterations in the hypothalamus/pituitary/ovary relationships. The result is a shifting of the function of the neuroendocrine system, which can impact cognitive and cardiovascular function, bone density, and the risk of many age-related diseases. Figure 32.3 describes the interrelationships among various components of the neuroendocrine system in female metabolism. As Figure 32.4 shows, when a woman ages and goes through menopause, her levels of estrogens, follicle-stimulating hormone (FSH), and luteinizing hormone (LH) change dramatically.

Disturbed sleep is one feature associated with the alteration of neuroendocrine function in women moving into menopause. The sleep cycle, an important circadian rhythm that results in repair of cellular damage incurred throughout the day, is initiated by cyclical secretions of the pineal hormone melatonin. Melatonin secretion can decrease dramatically with age³²¹ and with disease.³²² Melatonin is known to be a very effective oxygen radical scavenger and therefore may help protect the brain against oxidative injury.^{323,324}

Figure 32.3 The female neuroendocrine system

Figure 32.4 Female homeostat

Melatonin also has a very important effect on setting the “biological clock” of the hypothalamus. Indirectly, therefore, it influences estrogen secretion and metabolism. Normal aging is associated with both subjective and objective alterations in sleep quality in aging women and men as a consequence of changes in neuroendocrine function. The pineal release of melatonin is only a part of this story. Among the most common changes in sleep in aging individuals are decreased deep sleep (stages 3 and 4 or delta), poor slow-wave sleep, and an increase in the number of nocturnal awakenings.³²⁵

A report in 2000 indicated that poor slow-wave sleep results in lowered output of growth hormone and increases in evening cortisol output.³²⁶ It appears from this research that poor sleep quality reduces growth hormone output during the important evening hours, while increasing adrenocortical output. This may argue strongly for sleep therapy and/or melatonin being of primary importance in the management of some symptoms associated with neuroendocrine aging.

The functional medicine approach to improvement of circadian rhythms and their relationship to neuroendocrine function are beautifully explained in *The Circadian Prescription* by Sidney Baker, MD.³²⁷ In this book, he presents the concepts of rhythmic balance using food, nutrients, exercise, and breathing in setting the body’s cycles such as waking, sleeping, and secretion. As an addendum to the prescription for sleep hygiene, melatonin has been used successfully as a supplement in the sleep cycle at doses from 0.1 to as much as 10 mg per day.³²⁸

Summary

This discussion focused on a few topics that exemplify how important an understanding of cellular messaging is in the functional medicine approach to improving endocrine function. We have emphasized the value of modifying nutrition, lifestyle, and environment in controlling hormone-related, age-dependent disorders. The modulation of neuroendocrine messenger sensitivity, immune signaling, and cellular response can have a significant impact on many age-related conditions. Even with the recent explosion of information about the functional aspects of thyroid hormone and its metabolites, the field of functional endocrinology is still in its infancy. The strength of the model is its ability to identify important interconnections among different endocrine functions and to describe how they relate to modifiable environmental, lifestyle, and nutritional factors. The weakness of the model is that these interventions have generally not been subjected to large-scale, long-term, rigorous controlled clinical trials to examine how reproducible the effects are in patients, as well as which factors may be most important to consider when evaluating hypothalamic-pituitary-thyroid-adrenal (HPTA) axis function.

One can hope that such research will be done. However, without a significant financial incentive (as is present with pharmaceutical interventions), it may be a long time before we have definitive evidence. In the meantime, we use the emerging science, the functional medicine matrix, and the logic of the “interconnected web” to highlight viable new directions in the eternal struggle to relieve suffering and improve health. There is much we can do, even with incomplete and imperfect knowledge.

The Hypothalamus-Pituitary-Adrenal Axis

Michael Lumpkin, PhD

Introduction

The bodies and minds of humans and all living creatures are constantly subjected to changing circumstances in the outside world, as well as to changes occurring inside their bodies. When these alterations—whether internal, external, or both—perturb the balance of biochemical and physiological processes that maintain the baseline activities of normal organ, tissue, and gene function, physiologists refer to such challenges to normal balance as stress. The situations or events that cause stress can be of physical, metabolic, psychological, or emotional origin. The stressors themselves can be acute and short-lived or they can be chronic, persistent, and unrelenting. When an individual experiences an acute stressor, a coordinated series of nervous, endocrine, and immune system responses are put into play to ensure the immediate survival of the individual as the internal and/or external environment changes. At the core of this critical response is the hypothalamus of the brain. The hypothalamus is the **integrative** center of the central nervous system (CNS) because it monitors neuronal, hormonal, metabolic, and immune signals arising from inside the body and compares these inputs to information being sent to it from inside and outside the body by various receptor systems for temperature, pain, pressure, electrolyte, and metabolite concentrations, and other functions. Further, the state of mind—whether one is fearful, agitated, depressed, angry, happy, amused, or contented, for instance—is also perceived by higher brain centers, and this information is projected to the hypothalamus for processing and comparison to the baseline activities of the other organ systems being monitored.

Three components of the hypothalamus lie outside the blood-brain barrier (BBB), namely, the median eminence (ME), the organum vasculosum of the lamina terminalis (OVLT), and the posterior pituitary gland (or neurohypophysis—a downgrowth of median eminence neuronal tissue). Because these portions of the hypothalamus are exposed to blood, they are able to detect the concentrations of many blood-borne solutes including glucose, electrolytes (especially sodium), fatty acids, amino acids, water- and fat-soluble hormones, neu-

rotransmitters, peptides, cytokines, chemokines, and many other substances as well.

The hypothalamus is uniquely suited to its monitoring and integrative functions for several other reasons:

- It receives direct neuronal inputs from the lower brain centers such as the midbrain and spinal cord, and from higher brain areas such as the cingulate cortex and hippocampus.
- It produces the “master” neurohormones—the releasing factor hormones—that ultimately govern the stress hormone response, the reproductive axis, the metabolic hormones including thyroid hormones, the growth regulating axis, lactation, water and electrolyte balance.
- The hypothalamus regulates sympathetic and parasympathetic outflow to the organs, tissues, and blood vessels in the periphery of the body.
- The hypothalamus regulates feeding, appetite, drinking, sex behaviors, emotions, and biological rhythms in concert with other CNS and hormonal activities.

The hard wiring of the hypothalamus to other brain structures via well-known neuronal projection pathways provides the anatomical substrates for communicating conscious thoughts, emotions, and memories to the hypothalamic integrator and governor of the so-called vegetative or visceral functions.³²⁹ In other words, the hypothalamus, with its neuroendocrine primacy and its extensive CNS connectivity, forms a neuroanatomical basis for the mind-body (psychosomatic) connection.

The Hypothalamus and the Limbic System

The specific CNS pathways that subserve the mind-body connection are included in the limbic system,³³⁰ in which the hypothalamus occupies a pivotal position. Information from the neocortex, where rational, factual thought takes place, flows into the cingulate cortex lying above the corpus callosum. From the cingulate gyrus, cortical nerve fibers project to the hippocampus where the learning and memory of new information are transferred to long-term memory.³³¹ Additional cortical projections lead to the amygdala where emotional responses are attached to the factual information and memory of past events.³³² Stated differently, the factual information arriving at the hippocampus and amygdala is placed into an interpretable and familiar context. This collective information is then projected into the hypo-

thalamus via the fornix, the stria terminalis, and the amygdalo-fugal pathways.³³³ At this point, the hypothalamus and its various intercommunicating regions (nuclei) with their respective releasing factor (hormone) neurons will elicit the specific hormonal, autonomic, metabolic, and behavioral changes that are appropriate for the physical or emotional stress being experienced. Much of the time, individuals are quite unaware of these autonomic (automatic), visceral alterations in the body's physiology. However, because of projection pathways (called the mammillo-thalamic tract) exiting from the hypothalamus, and the relay of this information to the thalamus and from the thalamus via thalamo-cortical efferents arriving back at the cerebral cortex, individuals may become aware of changes in their physiological responses to stress. This increased perception of arousal may manifest as changes in the rate of respiration, muscular tremors due to the release of sympathetic catecholamines, increased mentation and alertness, increased body temperature and perspiration, cold hands, dry mouth, changes in appetite and food preferences, increased thirst, and bowel discomfort. A person may choose to act upon or moderate these responses. The neuronal pathways of connectivity described above and their linkages to hypothalamic/autonomic signaling may provide the basis for the effectiveness of mind-body relaxation techniques such as biofeedback to address stress-related pathologies.³³⁴

The Hypothalamic-Pituitary-Adrenal Axis

In order to understand how so much information is coordinated by the hypothalamus, it is helpful to review the elements of the hypothalamic-pituitary-adrenal gland axis. The parvocellular neurons of the paraventricular nucleus (PVN) of the hypothalamus elaborate the “master” stress hormone, a 41-amino acid neuropeptide known as corticotropin-releasing hormone (CRH) or factor (CRF).³³⁵ When an individual is exposed to stressful stimuli—some of which may be physical such as pain, trauma, infection, hypotension, exercise, or hypoglycemia; or others that may be psychological in nature such as bereavement, fear, personal loss, or anger—the release of hypothalamic CRH is stimulated.^{336,337} The CRH in turn is released into the portal blood vessels of the ME and is carried by venous blood flow to the corticotroph cells of the anterior pituitary gland. There, the CRH binds to its receptor on the corticotrophs and stimulates

the ultimate production and release of adrenocorticotrophic hormone (ACTH). The ACTH enters the systemic circulation and reaches the adrenal cortex of the adrenal gland, where it stimulates the synthesis of the glucocorticoid hormone cortisol and also androgenic hormones such as androstenedione and dehydroepiandrosterone (DHEA), both of which may ultimately be converted into the more potent testosterone or dihydrotestosterone (DHT) in peripheral tissues.

Cortisol acts as an important stress hormone because it maintains blood glucose levels during a stressful “fight or flight” challenge. During stress, as more demands are placed on the body, more metabolic fuel is consumed; yet, a critical amount continues to be needed to ensure normal brain function and to supply activated organs such as the heart, lungs, and skeletal muscle with a renewable supply of substrate. In addition, the cortisol also participates with aldosterone (the mineralocorticoid hormone) in driving sodium reabsorption by the kidney tubules. This serves the important function of conserving electrolytes and water within the vasculature to help maintain blood and perfusion pressures to critical organs and tissues that are participating in the fight or flight reactions. During the stress response, the blood concentrations of cortisol will rise until the cortisol starts to exert its negative feedback effect upon both the CRH neurons and the pituitary corticotrophs that manufacture ACTH, in order to reduce their increased levels of secretion back to their normal baseline.³³⁸ This homeostatic mechanism, when working correctly, prevents overproduction or prolonged elevations in CRH, ACTH, and cortisol.³³⁹ Thus, metabolic substrate is only mobilized when there is a specific need during the stress response.

When an individual experiences chronic stress along with maladaptive responses or a lack of coping, cortisol levels may remain inappropriately elevated due to persistent stimulation of the CRH-ACTH-cortisol axis. Metabolically, this can take a toll on the organism. The ongoing high concentrations of cortisol may keep blood glucose levels high for prolonged periods, cause redistribution of fat from the thighs and buttocks to the abdominal and cervical regions (“buffalo hump”) due to mobilization of free fatty acids; cause insulin resistance to develop; cause fluid retention and hypertension; produce proteolysis in muscle, bone, and connective tissues; and inhibit peptide and protein hormone formation (especially by the pituitary gland).³⁴⁰ The persistent

presence of increased cortisol will also have a profound inhibiting effect on immune system capabilities.³⁴¹ Elevated cortisol concentrations can decrease the number and functions of blood lymphocytes, eosinophils, basophils, monocytes/macrophages, and neutrophils. Further, cortisol can inhibit the production of immune cell-signaling molecules such as the proinflammatory cytokines interleukin (IL)-1, IL-2, IL-2 receptor, IL-6, tumor necrosis factor (TNF), and gamma interferon. Chronically elevated glucocorticoids can also decrease antibody and immunoglobulin production. Consequently, chronic activation of the HPA axis is associated with the development and worsening of chronic infectious diseases.

CRH as a Neurotransmitter

While CRH is best known for its neuroendocrine role in stimulating ACTH secretion from the anterior pituitary gland, CRH also acts as a neurotransmitter by stimulating sympathetic outflow from the brain and spinal cord and simultaneously inhibiting the outflow of parasympathetic activity to the periphery.³⁴² Part of the sympathetic response is to stimulate the adrenal medullary release of the catecholamines epinephrine and norepinephrine into the circulation. Additionally, sympathetic nerves that innervate visceral organs and tissues such as the heart, coronary arteries, peripheral blood vessels, kidney, lungs, pancreas, gastrointestinal tract, and gonads, will release their contents of norepinephrine and neuropeptide Y at these sites. The overall result is to accelerate cardiopulmonary activity by increasing heart rate, strength of cardiac contraction, arterial vasoconstriction, and blood pressure, with shunting of blood from the splanchnic vasculature to skeletal muscles, heart, and brain, and increasing the rate and depth of respiration.³⁴³ Stimulated sympathetic catecholaminergic inputs to the liver and adipose tissue result in enhanced glycogenolysis and lipolysis, thereby supplementing the glucose and free fatty acid-elevating action of cortisol. The integrated view is that CRH is acting in its neuroendocrine capacity to supply the main metabolic substrates (via its cortisol and catecholamine stimulating action) for the CRH-directed trigger of visceral organ stimulation upon sympathetic nervous system activation after physical or psychological challenge. Other CRH-directed sympathetic targets involve the stimulation of the renal renin-angiotensin-aldosterone system and the neurosecretion of antidiuretic hormone (arginine vasopressin). These sym-

thetically driven hormones will act in concert with cortisol and the catecholamines to defend against volume depletion and hypotension during any homeostatically threatening situation.

Stress-related activation of CRH also alters the ratio of sympathetic to parasympathetic inputs to the gastrointestinal tract.³⁴⁴ The net outcome for the stomach is an inhibition of gastric contractility and decreased emptying, leading to sensations of fullness and bloating. In the case of the colon, accelerated motility with rapid transit times for chyme and poor absorption of nutrients and water is the result. Diarrhea and inflammation of the bowel can result if the stress is of sufficient intensity and length. It has been suggested that this mechanism of stress may contribute to the development of irritable bowel syndrome and the exacerbation of Crohn's disease.³⁴⁵ Such inflammatory states of the bowel may lead to the "leaky gut" syndrome with mal-digested food antigens provoking inappropriate immune responses in the form of food reactions. (These issues are explored in depth in Chapters 28 and 31.)

Sympathetic noradrenergic nerve fibers also innervate immune organs such as the thymus gland, spleen, lymph nodes, bone marrow, and intestinal Peyer's patches.³⁴⁶ Norepinephrine-containing nerve fibers have been seen in contact with thymocytes, B lymphocytes, and macrophages.³⁴⁷ In fact, alpha and beta adrenergic receptors have been identified on these immune cells. In general, activation of the sympathetic nervous system or administration of epinephrine produces leukocytosis, lymphopenia, and suppression of natural killer (NK) cell activity. In other words, the action of catecholamines is to inhibit lymphocyte proliferation and suppress the immune response. Experimentally, it has been observed that the stress of foot shock, cold exposure, maternal deprivation, and fear may cause thymus gland involution, decreased lymphocyte proliferation and cytotoxicity, and less antibody production. Conversely, the interruption of sympathetic innervation to immune organs results in lymph node, spleen, and bone marrow cell proliferation, in addition to antigen-provoked immunoglobulin production.³⁴⁸ Consequently, prolonged stress that activates CRH-driven sympathetic outflow would be expected to lead to greater susceptibility to disease, infections, and cancer in human patients with a chronically suppressed immune system.³⁴⁹

CRH and Behavior

CRH neurons are not only located in the hypothalamus but are also found in the dorsal raphe nucleus, the hippocampus, the bed nucleus of the stria terminalis, the reticular formation, periaqueductal gray, locus coeruleus, septum, and telencephalon. Due to their presence in these areas of the brain and their involvement in regulating autonomic nervous system activity and hormone secretion, CRH is well-positioned to participate in coupling these neurochemically-governed responses to corresponding stress-related behaviors. It has been observed in animal models that CRH injected into the brain produces behaviors that are typically seen when animals and humans experience stressful events.^{350,351}

- Increased locomotor activity (to rapidly escape danger)
- The startle response (to orient to a threat)
- An anxiogenic-like effect
- A dose-dependent facilitation of stress-induced fighting
- A dose-dependent taste and place aversion (An interest in eating may decline and unfamiliar and threatening locations will be avoided.)

In addition, when CRH is injected into the brains of animals, they display the same signs and symptoms as humans who are suffering from major clinical depression,³⁵² including a lack of interest in pleasurable activities; significant changes in weight and appetite; sleep disturbances; psychomotor agitation; fatigue; and self-destructive behavior (suicidal tendencies in humans).

That CRH is indeed driving much of this symptomatology is evidenced by 1) the fact that depressed humans also have sustained 24-hour elevations of plasma cortisol, and 2) the blocking of depressive states by administration of CRH receptor antagonists in experimental animals.³⁵³ Thus, it is no surprise that patients with chronic diseases may be depressed and that chronically depressed patients may be suffering from a multitude of disorders, all of which are likely contributed to by chronic stimulation of the HPA axis. In fact, Chrousos and Gold have developed a list of chronic disease states that are associated with increased HPA (high cortisol present) or decreased HPA (low cortisol present) activity.³⁵⁴ Table 32.2 shows conditions associated with high and low HPA activity. Clearly, if the course of chronic stress and its associated disease states could be addressed at the neuroendocrine and behavioral levels

of CNS CRH overstimulation, a number of downstream pathologies might be favorably impacted.

Table 32.2 Conditions Associated with HPA Axis Dysregulation

Associated with High HPA Activity	Associated with Low HPA Activity
Chronic stress	Adrenal insufficiency
Melancholic depression	Chronic fatigue syndrome
Anorexia nervosa	Fibromyalgia
Diabetes mellitus	Postpartum depression
Syndrome X	Post-traumatic stress syndrome
Premenstrual syndrome	Exacerbation of rheumatoid arthritis

HPA Axis and Cytokines

Immune cells produce and secrete soluble mediators known as proinflammatory and anti-inflammatory cytokines.³⁵⁵ The proinflammatory cytokines not only allow immune cells to communicate with each other and mount a vigorous immune response, but they also permit the immune system to communicate with neuroendocrine systems.³⁵⁶ Proinflammatory cytokines such as IL-1, IL-2, IL-4, IL-6, and TNF are, of course, variously made by macrophages, monocytes, lymphocytes, and natural killer cells. In response to foreign antigens and pathogens (infectious stress), inflammation, trauma, and psychological stress, immune cells will release their large polypeptide, proinflammatory cytokines and these will enter the systemic circulation, thereby gaining access to the hypothalamus either through specific transport mechanisms^{357,358} or by passing through the circumventricular organs (i.e., the OVLT and ME) where the blood-brain barrier is absent.³⁵⁹ It also happens that microglial, astroglial, endothelial, and neuronal cells in the hypothalamus synthesize their own IL-1, IL-2, IL-6, and TNF.³⁶⁰ Interestingly, systemically circulating cytokines produced in response to stress can signal the activation of hypothalamically-produced cytokines. Each of the proinflammatory cytokines discussed here has been shown to stimulate CRH activity in the hypothalamus.³⁶¹ Chronic

elevations of these cytokines in the brain not only raise CRH output, but also can cause anorexia, fever, fatigue, dementia, and even neuronal death.^{362,363,364} With increased CRH activity, more ACTH (and thus cortisol) is produced. An important function is served by this cortisol increase following activation of immune cell cytokine production. When homeostasis is operating correctly, the rising levels of corticosteroid will eventually dampen the very robust immune response by reducing the proliferation and secretion of cytokines from immune cells. In the short term, this is useful because it prevents the increased immune response from running amok.³⁶⁵ If the immune response were to go unchecked, it could trigger autoimmune events and produce unhelpful inflammatory responses during a fight or flight situation.³⁶⁶

Sometimes, though, individuals are exposed to persistent stressors without relief. Such situations will provide more or less continuous stimulation of the CRH-ACTH-cortisol axis. The ongoing high levels of cortisol may cause damage and death to the neurons in the hippocampus that mediate cortisol negative feedback on CRH neurons. In other words, with unregulated or untreated chronic stress, excessive exposure to cortisol may disable the negative restraint on stimulated CRH secretion.³⁶⁷ The consequence of this may be to produce many of the pathologies associated with CRH-driven activities. For instance, excessive CRH acting in the brain may lead to depression and other behavioral disorders. This might be accompanied by elevated cortisol that causes metabolic derangements such as hyperglycemia, insulin resistance, hypertension, and other symptomatology of the Cushingoid condition. The presence of too much glucocorticoid may impair an individual's immune status, leading to the development of infectious conditions and memory impairment due to loss of hippocampal neurons.³⁶⁸

The HPA axis is in many ways the conductor of the homeostatic symphony. It is probably apparent at this point that the CRH of the brain is intertwined in some way with virtually every physiological system of the body. Polycystic ovary disease (PCOD) is an example of chronic illness that can be used to illustrate the interconnected web of physiological systems. In fact, almost any chronic, difficult-to-treat condition might share in the cascade of events to be described. **The main principle to be learned is that any chronic perturbation to one element of the system will ripple through other**

components of the web. This being the case, one must try to address the initial causes of the perturbation at the beginning of the cascade to achieve the best outcome. Of course, there may still be much utility in addressing downstream symptoms to provide some immediate relief, but the most long-lasting solutions to chronic disease probably require the most comprehensive interventions aimed at the top of the pathological cascade.

Polycystic Ovary Disease: A Possible Scenario

Many women with polycystic ovary disease (also known as polycystic ovary syndrome, or PCOS) also suffer from anxiety and depression. In many instances, these women are overweight and develop insulin resistance. They have become amenorrheic or oligomenorrheic, which results in infertility. How might all of these symptoms be related?

If depression and anxiety precede the PCOD, we could speculate that some manner of life stress, without treatment or coping skills present, stimulates the overproduction of CRH in the brain and cortisol in the body. The elevated CRH drives the development of clinical depression, elevated adrenal cortisol, and androgen production. The high cortisol levels raise blood glucose levels. The persistence of high glucose concentrations leads to excessive insulin secretion. Excessive insulin secretion may cause insulin resistance to develop. With insulin resistance comes even more pancreatic production of insulin in an attempt to compensate. The high cortisol and insulin concentrations work synergistically to cause centripetal obesity characteristic of the metabolic syndrome (syndrome X). The excessive insulin, either through insulin or insulin-like growth factor-1 (IGF-1) receptors on ovarian stromal and thecal cells, stimulates more androgen hormone production. The excess androgen is converted into estrone by the extra adipose tissue of obesity. The elevated estrone levels disrupt the normal pulsatile secretion pattern of gonadotropin-releasing hormone (GnRH). This disruption alters the proper ratio of luteinizing hormone (LH) to follicle-stimulating hormone (FSH) release from the pituitary gland. The result is that too much LH is made and not enough FSH. The elevated LH stimulates further excessive androgen production, which compounds the hyperandrogenism being driven by the increased insulin concentrations. In the face of hyperandrogenism, high estrone, and disrupted LH/FSH ratio,

normal menstrual cycles cease with amenorrhea, anovulation, and infertility being the result. The patient may display virilizing characteristics due to high androgen production such as acne, hirsutism, clitoral enlargement, and male hair distribution.³⁶⁹

Figure 32.5 graphically displays this sequence of events.

Figure 32.5 The HPA cascade in PCOD

Clinical Approaches to PCOD

While the classical approach to the treatment of this disease has been to use estrogen agonists and antagonists and perhaps androgen blockers, these interventions may be rather remote from important initiating factors in the cascade of decompensating events. A

more comprehensive approach might involve lifestyle, dietary, and nutraceutical interventions that target more of the interconnected web of pathophysiological associations than treatment of the hyperandrogenization alone is likely to achieve.

Relaxation induction methods such as biofeedback, autogenic training, and mindfulness meditation^{370,371} have been shown to reduce parameters indicative of sympathetic activation such as vasoconstriction of peripheral blood vessels, accelerated heart rate, and hypertension. Because increased sympathetic outflow is generated by CRH activation, a reduction of these parameters through relaxation methods would imply a reduction in CRH activity in the hypothalamus. From this would follow a lowering of cortisol, glucose, and insulin levels, which would reduce the overstimulation of androgen production by the adrenal cortex and the ovary. Then, less estrone would be synthesized by adipose tissue. The lowering of androgen and estrone levels could set the stage for a reestablishment of the normal pulsatile secretion of GnRH by the hypothalamus, and thus normal LH and FSH secretion patterns, followed once again by normal ovulatory cycles. All the while, the patient's psychologic and physiologic states are being improved.

Dietary and nutraceutical approaches might include increased intake of complex carbohydrates and fiber, and decreased intake of refined carbohydrates, to address the mood and metabolic disorders.³⁷² Chromium administration could aid both the depressive aspects of the condition as well as the insulin resistance issue.³⁷³ Increased consumption of soy could inhibit the aromatization of excess androgen into estrone and improve the metabolic conversion of the excess estrogen into the 2-OH series rather than the more carcinogenic 16-OH series.³⁷⁴ Increasing the intake of omega-3 fatty acids could combat the proinflammatory mediators brought on by the excess body fat and insulin resistance that are characteristic of PCOD. Further, omega-3 fatty acids combat depressive mood disorders.³⁷⁵

HIV/AIDS: A Probable Scenario

Patients suffering from HIV/AIDS experience not only the pathophysiological stress of the infection itself, but also the psychological stress of having a chronic, difficult-to-manage disease that carries a social stigma. In HIV/AIDS, inflammatory mediators are produced and lymphocyte numbers and function are

impaired. The AIDS virus in peripheral and brain tissues results in significant production of the proinflammatory cytokines, especially IL-1 β , TNF- α , and IL-6.³⁷⁶ But the emotional stress of having this disease can also be expected to elevate proinflammatory cytokine levels. As described previously in this chapter, these cytokines will act upon the hypothalamus to stimulate the CRH-ACTH-cortisol axis,³⁷⁷ and will act on the brain directly to produce sensations of fatigue, lethargy, and cachexia—symptoms that are common in AIDS patients. It also happens that CRH neurons make synaptic contact with the GnRH neurons that govern LH/FSH and thus gonadal steroid hormone synthesis. CRH axons project onto TRH neurons that govern TSH and thus thyroid hormone (T₄/T₃) synthesis by the thyroid gland. Furthermore, CRH nerve cells make synaptic contact with the GHRH cell bodies in the hypothalamus that govern growth hormone (GH) secretion and thus growth and repair of bone and soft tissues.³⁷⁸

When chronic HIV stress activates the CRH neurons, the GnRH-gonadotropin-sex steroid axis, the TRH-TSH-thyroid hormone axis, and the GHRH-GH-growth axis are all inhibited or impaired to varying degrees. In an acute stress response, this shifting of metabolic support away from reproductive and growth-promoting activities and toward the support of critical brain, heart, and skeletal muscle function enhances the likelihood of survival during a fight-or-flight situation. However, in a chronic condition such as AIDS, the persistent stimulation of the cytokine-CRH system and its negative impact on sex steroid, thyroid hormone, and GH activities can have devastating consequences that worsen the morbidity and mortality of the condition. For instance, the ongoing elevations in cortisol will further impair the protein synthesis of the pituitary hormones. This, of course, aggravates the already degraded production of hormones of the reproductive axis. In male patients with HIV/AIDS, the reduced production of testosterone by the testis may not only cause impotence, loss of libido, and infertility, but the diminution of this anabolic steroid may also contribute to the protein wasting that is often seen^{379,380} and that is directly related to the imminence of death from the disease.³⁸¹

Severely ill AIDS patients will also experience the “euthyroid sick syndrome,” involving reduced production of TRH and impaired response of the thyroid gland to TSH.³⁸² The net result is a state of hypothyroidism that produces the well-known symptoms of lethargy,

weakness, cold intolerance, dryness and pallor of skin, edema, and slowed mentation. The hormone deficiencies noted above may be accompanied by insufficient GH production due to the direct actions of the HIV virus to inhibit hypothalamic GHRH activity and because proinflammatory cytokines (such as IL-1) and CRH exert direct effects to inhibit GHRH and to stimulate somatostatin release from the hypothalamus.^{383,384,385} Since GH is a protein anabolic hormone that promotes the growth of body tissues, its reduction in AIDS patients undoubtedly contributes to the wasting of lean body mass in adults and the failure of growth in children with this disorder.³⁸⁶ The ongoing GH deficiency may, interestingly, also exacerbate the state of immune deficiency, since GH has been shown to support the integrity and function of immune tissues and cells.³⁸⁷

Clinical Approaches to HIV/AIDS

There is no question that the most effective treatment for HIV infection at this time continues to be the triple therapy approach that includes some combination of nucleoside reverse transcriptase inhibitors and non-nucleoside reverse transcriptase inhibitors, or protease inhibitors.³⁸⁸ While this treatment addresses the goal of controlling the proliferation and infectivity of the virus, it does not address the impact of the psychological and physical stress of the already extant disease state. As with the treatment paradigm in PCOD, there exist additional behavioral, dietary, and nutraceutical approaches that could address a number of the stress and neuroendocrine disorders that accompany this insidious disease, thus reducing the overall impact of the infection.

HIV patients could benefit from various relaxation induction methods that would lower CRH output, thereby reducing stress hormone levels (especially cortisol) and managing their metabolic substrates more efficiently. This would also reduce the tendency for HIV patients receiving highly active antiretroviral therapy (HAART) to gain abdominal fat mass at the expense of lean muscle mass.

Relaxation-induced reductions in stress-elevated cytokines and CRH would also decrease the inhibitory tone exerted over LHRH, GHRH, and TRH neurons, possibly leading to increased pituitary gland output of LH, FSH, GH, and TSH that might restimulate their peripheral targets. If that goal could be achieved, it would increase the chances of elevating anabolic hormone lev-

els of GH and testosterone (both lipolytic hormones), thereby enhancing the possibility of maintaining lean body mass and decreasing the drug-induced fat deposition. Poor wound healing would then be expected to improve due to the protein synthesis actions of these hormones. The improvement in TRH-TSH-thyroid hormone production would also be expected to increase the energy level and mental abilities of such patients. More GH production might enhance the immune status of the individual. Because the elevated proinflammatory cytokine levels in the brains of HIV patients may also cause neuronal damage and states of dementia to develop,³⁸⁹ any attempts to reduce stress-activated cytokine levels could prove beneficial in this disorder.

Proinflammatory cytokines also act in the brain to cause the manufacture of reactive oxygen species (oxygen radicals) and inflammatory prostaglandins, which mediate many of the deleterious effects of the cytokines.³⁹⁰ Since this is a problem in AIDS, the administration of antioxidant vitamins could be beneficial. In particular, vitamins C, E, and B complex have been shown to be effective in improving neuropsychologic disorders.^{391,392,393} Most interestingly, this same combination of vitamins was recently demonstrated to delay the progression of HIV disease in women, most likely by exerting their antioxidant effects against the mediators of inflammatory processes.³⁹⁴ HIV patients could also benefit from the intake of omega-3 fatty acids to help repair and protect neuronal membranes damaged by inflammatory mediators and, as in PCOD, to improve the depressive state of the patient.

Due to the protein wasting of AIDS, supplementation with amino acids in the face of improved anabolic hormone status might enhance the likelihood of restoring lean body mass. If the supplementation includes such amino acids as phenylalanine, tyrosine, and L-tryptophan, which are precursors for the synthesis of norepinephrine, thyroxine, and serotonin, respectively, then both neurological and thyroid gland functions could be better supported, as would the interactions between thyroid hormone, the CNS, and neuroendocrine systems.

With AIDS dementia, there can be compromised memory function. This could be addressed through the use of *Ginkgo biloba* to improve impaired memory in states of dementia.³⁹⁵

Obviously, in both chronic disorders mentioned above, the approaches described are not complete or exhaustive, nor is the research base for such interventions very well developed. They are offered as examples of how to view chronic disease in a more integrated and connected fashion, using our understanding of underlying mechanisms and pathways to provoke alternate considerations when designing comprehensive care for multifaceted disease states.

Summary

Chronic disease states necessarily imply chronic disruptions to homeostasis. Or, more simply, chronic disease creates chronic stress for patients. Chronic stress involves both psychological and physical reactions, setting off a cascade of events that is common to many complex, long-lasting illnesses. At the heart of stress detection is the hypothalamus, the integrative control center of actual mind-body (or brain-body) functions. With chronic stress of any kind comes the production of proinflammatory cytokines that signal increased activity of the hypothalamic-pituitary-adrenal axis. The hormones of the corticotropic axis then coordinate and manage the further activities of the brain, other neuroendocrine axes, behavior, metabolic substrates, electrolyte and water balance, and the immune system, all done in proper coordination with the demands and feedback from other organ systems.

In the acute phases of the stress response, the integrated control of the organ systems by the hypothalamic CRH system will enhance the likelihood of survival of the organism. However, if the elements of the acute stress response are not appropriately moderated or reduced in a timely fashion, the lasting stimulation of proinflammatory cytokines and CRH sets off a cascade of pathophysiological events that will negatively impact virtually every organ system to a lesser or greater degree. In the past, the approach to such massive decompensation of the patient was to treat each end-of-cascade symptom as a separate entity. However, this practice does not address the initiators of the cascade, overlooks ancillary problems, and often does not provide satisfying results to patients or their physicians. A better understanding of the factors that govern the initiation and mediation of this common cascade

should help clinicians find healthier and more comprehensive avenues for managing chronic illnesses. An appreciation of the hypothalamic-pituitary-adrenal axis in stress responses and functional medicine philosophy should facilitate this goal.

Managing Insulin and Glucose Balance
Dan Lukaczer, ND

The balance between insulin and glucose is quite possibly the single most important clinical issue facing the practicing clinician today. It is clear that a substantial and growing body of evidence suggests that insulin sensitivity problems are an underlying causal factor in cardiovascular disease, stroke, type 2 diabetes, polycystic ovary syndrome (PCOS), and certain forms of cancer. Insulin resistance and hyperinsulinemia result in a cascade of biological effects; this complicated pathophysiology has been described elsewhere in this book. Here we will review a practical clinical approach to the diagnosis and treatment of this condition.

Clinical and Laboratory Diagnosis

Insulin resistance syndrome (IRS) refers to a cluster of symptoms characterized by varying degrees of glucose intolerance, abnormal HDL cholesterol and/or triglyceride levels, high blood pressure, and upper body obesity. The most obvious sign suggestive of IRS is upper body adiposity and elevated body mass index (BMI). Waist circumference >88 cm (34.5 in) in women and >102 cm (40 in) in men is an important and simple assessment.³⁹⁶ However, care must be taken not to conclude that insulin resistance is exclusively seen in obese subjects, since greater than 50% of individuals with IRS are not classified as obese, and individuals may have normal insulin sensitivity with elevated BMI.³⁹⁷ Recently, the Third Report of the National Cholesterol Education Program Expert Panel (2001) outlined specific criteria to diagnose metabolic syndrome.¹ These criteria are listed in Table 32.3.

¹Metabolic syndrome does not completely encompass all aspects of insulin resistance. However, the parameters used to describe metabolic syndrome are broadly applicable. Metabolic syndrome is now widely used in research and, therefore, has become a well-recognized definition that is often used interchangeably with insulin resistance syndrome.

Table 32.3 Criteria for the Diagnosis of Metabolic Syndrome

A patient must have three or more of the following five criteria to be diagnosed with metabolic syndrome:
• Abdominal obesity: waist circumference >102 cm (40 in) in men and >88 cm (34.5 in) in women;
• Hypertriglyceridemia: ≥150 mg/dL (1.69 mmol/L);
• Low high-density lipoprotein (HDL) cholesterol: <40 mg/dL (1.04 mmol/L) in men, <50 mg/dL (1.29 mmol/L) in women;
• Blood pressure: ≥130/85 mm Hg;
• Fasting glucose: ≥110 mg/dL (≥6.1 mmol/L).
Published in the Third Report of the National Cholesterol Education Program Expert Panel, 2001.

Clinical observation may suggest other signs and symptoms helpful in identifying an individual with insulin resistance. Table 32.4 provides a list of commonly encountered signs and symptoms that may offer additional information in a clinical assessment.

Table 32.4 Other Laboratory and Clinical Signs and Symptoms that May Be Suggestive of IRS

Family history of diabetes
Gestational diabetes
Polycystic ovary syndrome (PCOS)
Infertility
Low birth weight
Sleep apnea
Sugar cravings and carbohydrate “addiction”
Sleepiness after a meal and insomnia relieved by snacking
Increased appetite following a high carbohydrate meal
Fatigue following high-carbohydrate meals
Hypoglycemia
Dietary history of high-refined carbohydrate intake
Resistant weight loss
Hirsutism, acne, and menstrual irregularities

Many individuals who develop insulin resistance maintain normal to near-normal fasting glucose control; two-hour postprandial glucose challenge test with a 75-gram glucose load may be marginally elevated, suggesting impaired glucose tolerance. Elevated fasting insulin, and/or two-hour postprandial insulin may also be important indicators of insulin resistance. However, after the onset of type 2 diabetes there may be a reduction in beta cell function and, eventually, a fall in insulin. In addition, several other laboratory signs may suggest an individual with subclinical IRS, or at high risk of developing

insulin resistance. Useful additional markers that suggest IRS include elevated triglycerides and depressed HDL (triglycerides-to-HDL ratio of >3).³⁹⁸ An elevated serum uric acid also appears to be associated with IRS. Recent literature also suggests a relationship between IRS and markers of inflammation, such as hsCRP.³⁹⁹

Clinical Intervention

It appears that at the core of insulin resistance is a defect in cellular sensitivity to insulin. As more light has been shed on this topic, this underlying metabolic dysregulation has become a focus for the clinician's attention.⁴⁰⁰ Although the cellular disturbance is not completely understood at the biochemical level, modifiable factors such as obesity, exercise, and nutrition appear to play a significant role. While genetic inheritance may determine propensity to the disorder, these modifiable factors should be addressed as part of any comprehensive clinical management strategy.

Exercise, Smoking and Obesity

Exercise has profound beneficial effects on insulin resistance and should be aggressively pursued. Numerous studies support the use of exercise in the management of this condition.^{401,402} Conversely, cigarette smoking plays a role in exacerbating insulin resistance in susceptible individuals.⁴⁰³ Therefore, in those individuals, smoking is particularly detrimental. Increased adiposity plays a pivotal role as well, especially when concentrated around the abdomen and upper body. Adiposity/obesity induces insulin resistance in peripheral tissues; thus, weight loss (specifically fat loss) is of prime importance, and has been shown (not surprisingly) to improve insulin sensitivity.^{404,405} Because of its anabolic activity, insulin and hyperinsulinemia secondary to insulin resistance may predispose to increased weight gain and difficulty with weight loss.⁴⁰⁶ Longitudinal studies suggest that elevated insulin levels may start in childhood, with fasting hyperinsulinemia serving as a predictor of increased body weight gain and obesity.^{407,408}

While adiposity is an important issue, not all insulin-resistant individuals are obese. Other factors are involved, and individuals may have normal insulin levels while still remaining overweight.^{409,410} The sensitivity of insulin to stimulate glucose uptake varies widely from person to person, with the degree of obesity as only one factor.⁴¹¹ Clearly, obesity, smoking, and

a sedentary lifestyle increase risk for insulin resistance and should be managed aggressively; however, they are not necessarily an essential characteristic of this complex syndrome.

Nutritional Modulation

In addition to appropriate lifestyle changes, insulin and glucose balance can be promoted through dietary adjustments and the use of select nutritional supplements. The relative amounts and types of carbohydrate, protein, fat, and fiber are all important factors that influence glucose availability and insulin secretion and therefore may be important in managing IRS. Dietary recommendations for patients with insulin resistance should be individualized, with consideration given to eating habits and other lifestyle factors. Nutritional supplement recommendations are then developed to meet treatment goals and desired outcomes. Monitoring metabolic parameters, including blood glucose, lipids, blood pressure, and body weight, as well as quality of life, is crucial to ensure successful outcomes.

Food as Medicine

Macronutrients influence both glycemic and insulin response. The ratio and type of macronutrients are important considerations, yet the dietary prescription remains controversial. A high-carbohydrate, low-fat diet for type 2 diabetics has been shown in some studies to produce adverse lipid and glycemic effects. High carbohydrate diets (60–70% carbohydrate) decrease insulin receptor numbers, probably as a result of the increased insulin cellular contact and resultant receptor downregulation.⁴¹² Some studies have shown that high-carbohydrate diets increase triglyceride and VLDL cholesterol levels, and elevate insulin and glucose concentrations in type 2 diabetics.^{413,414} Fat in general has been thought to have little insulinogenic effect. However, alterations in membrane lipid composition and membrane fluidity influence important cellular functions. Studies have suggested that there is an altered membrane dynamic in type 2 diabetics as compared to normal controls, which may influence insulin action. This underscores the importance of the physiochemical properties of the cell membrane to control the activity of membrane proteins such as insulin receptors. If the decreased response to insulin is, in part, the result of a defect in characteristics or functions of the receptor caused by altered membrane

fluidity, attending to membrane dynamics becomes an important therapeutic target.⁴¹⁵

Fatty acids within the phospholipid bilayer help to determine the physiochemical properties of membranes that, in turn, influence cellular functions, including hormone responsiveness. Dietary fat has been shown to determine to a large extent the composition of cell membrane phospholipids. It appears that direct alterations in the fat composition of the cell membrane can induce changes in insulin responsiveness. The long-chain polyunsaturated fatty acids (PUFAs) can modulate the function of insulin receptors and glucose transporters through effects on the physical properties of the surrounding lipid environment.⁴¹⁶ In cultured cells, increasing cell membrane content of PUFAs increases membrane fluidity, insulin binding to receptors, and insulin action.⁴¹⁷ In animal models it has been shown specifically that omega-3 fatty acids (explored in depth in Chapter 27) such as eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA) have a beneficial effect on plasma insulin and lipid concentrations.⁴¹⁸ Conversely, saturated fats and *trans* fatty acids decrease membrane fluidity and decrease binding of insulin to its receptors.^{419,420,421} When omega-3 fatty acids are substituted for other sources of fat in a high-fat diet, insulin resistance in skeletal muscle may be prevented.^{422,423} In human trials, monounsaturated diets appear to mitigate against these adverse changes as well.⁴²⁴ For these reasons, the high-monounsaturated fat diet (popularized as the Mediterranean Diet) has been proposed as an alternative to the high-carbohydrate diet. Studies using a lower carbohydrate, higher monounsaturated and polyunsaturated fat diet show decreased fasting glucose, insulin, and triglycerides.^{425,426,427} Most, but not all,⁴²⁸ studies have supported this conclusion.

Studies using dietary approaches to treat individuals with insulin resistance have been inconsistent. This may be explained in part by the wide range of physiologic effects that equal amounts of different carbohydrates may have on glucose regulation. This variation in response to carbohydrates has resulted in the study of the glycemic index (GI). The concept of GI developed as the result of intensive carbohydrate research showing that similar amounts of carbohydrate in foods did not elicit similar postprandial glycemic responses.^{429,430} The GI of a food is defined as the blood glucose response to a 50-gram available carbohydrate portion of that food expressed as a percentage of the response to the same

amount of carbohydrate from a standard food, which is either glucose or white bread. The GI value depends on a number of factors, such as degree of starch gelatinization, physical form of the food, acidity, food processing, and the presence, amount, and type of protein, fat, fiber, and available carbohydrate in the food. Of these, the effects of fiber and type of starch on glucose response deserve further mention.

It is well known that fiber plays an important role in affecting insulin and glucose response.^{431,432} High fiber, independent of total carbohydrates, has a beneficial effect on blood glucose control and atherogenic lipoproteins.⁴³³ It appears that soluble fibers in particular act favorably on blood insulin concentrations. Their mode of action appears to be in slowing gastric emptying and, to a lesser extent, inhibition of starch degradation in the upper small intestine.⁴³⁴ The type of starch is also an important issue in the GI tract. Because of its structure, the starch amylose, as opposed to the more common amylopectin, has a significant positive impact on insulin response in both animal and human studies.^{435,436} Insulin and triglyceride levels were reduced in individuals placed on a high-amylose diet, suggesting a beneficial effect on factors involved in insulin sensitivity.⁴³⁷ Studies also suggest that a low-GI dietary plan helps control blood sugar levels and leads to decreased caloric intake.⁴³⁸ Overall, studies in both men and women show that diets with a low GI are associated with a lower risk of developing type 2 diabetes and heart disease.^{439,440} Recently, the United Nations World Health Organization has recommended that all people base their diets on low-GI foods.

Protein may also have an impact on insulin and glucose response. Some studies have shown protein ingestion results in a blunting of the glucose rise and insulin response in normal individuals.⁴⁴¹ However, more recent work suggests that protein-rich foods may vary in their effect, although in general they exhibit a low to modest response.⁴⁴²

Selected Nutrients and Phytonutrients

Research has shown that many vitamins, minerals, and certain phytonutrients have the potential to improve insulin sensitivity and stabilize blood glucose levels. The mechanism of action for many of these substances has not been completely elucidated and remains under intense investigation. The following is not an all-inclusive list, but highlights some key nutrients and

phytonutrients that show significant promise in their ability to modify insulin resistance.

Magnesium. Magnesium plays an important role in glucose homeostasis by altering both insulin secretion and action. Adequate intracellular magnesium concentrations may therefore allow for improvement of glucose handling.⁴⁴³ Daily magnesium supplements appear to improve the behavior of hormone receptors and improve glucose transport into the cell.⁴⁴⁴ Tissue levels of magnesium are often low in diabetics and in individuals with normal glucose disposal.^{445,446,447} Low intracellular magnesium results in impairment of insulin action and a worsening of insulin resistance in hypertensives and type 2 diabetics.^{448,449} A low magnesium concentration in nondiabetic subjects has been associated with relative insulin resistance, glucose intolerance, and hyperinsulinemia.⁴⁵⁰

Chromium. A great deal of work has been done on the relationship between chromium and glucose tolerance.^{451,452} Certain lipophilic forms of chromium have been shown to increase membrane fluidity and insulin-mediated glucose uptake in cultured cells and animal models. Chromium may affect the action of insulin by influencing the rate of insulin internalization, which may regulate the synthesis or insertion of insulin receptors into the plasma membrane.⁴⁵³ Chromium functions physiologically to promote the insulin responsiveness of skeletal muscle, and probably adipocytes as well. Chromium deficiency is also associated with elevated blood glucose levels, hypercholesterolemia, and the development of aortic plaques.⁴⁵⁴ Beneficial effects of supplemental chromium on serum lipids have been reported in controlled trials.⁴⁵⁵ Recent studies have examined the use of chromium in type 2 diabetics and suggest that fasting and postprandial blood sugar and insulin, as well as glycated hemoglobin, are significantly reduced with supplementation.^{456,457}

Vanadium. Vanadyl sulfate is a salt of the mineral vanadium. Although vanadium is ubiquitous in the environment, its essentiality in humans has not been established. However, results from deficiency studies are highly suggestive of an essential role for vanadium as a nutrient in humans.⁴⁵⁸ In both animal and human studies, vanadate and vanadyl forms of vanadium have demonstrated insulin-like effects on glucose metabolism.⁴⁵⁹ However, its exact physiological action is not completely understood. It does not replace insulin by its action, but rather appears to activate cellular insulin

receptors either by phosphotyrosine phosphorylation or via inhibition of phosphotyrosine phosphatase enzymes.^{460,461} This leads to an increase in glucose transporter proteins (GLUTs) in the plasma membrane, which are essential for the transport of glucose into the cell. In human trials, vanadium has been shown to improve insulin sensitivity in type 2 diabetes at dosages of 100–125 mg/day.^{462,463,464} There is currently no RDA for vanadium. The upper safe limit has been set by the U.S. Food and Nutrition Board at 1.8 mg/day; therefore, ingesting 50–100 mg long-term may be dangerous. In fact, a recent study suggested chronic exposure to high levels of vanadium reduces cognitive abilities.⁴⁶⁵ While this was not from oral ingestion of vanadium, caution is called for in long-term supplementation with high levels of vanadium, and supplementation should be strictly monitored.

Biotin. Biotin is a vitamin that can be synthesized by microflora in the colon. Biotin deficiency has been suggested to result in an impairment of glucose tolerance. Animal studies suggest that a high biotin intake can improve the metabolism and/or utilization of glucose without the acceleration of insulin secretion from the pancreas.⁴⁶⁶ Human studies indicate that intravenous biotin may be useful in the management of diabetes.⁴⁶⁷ Additionally, it has been observed that high dose oral biotin (9 mg/day in divided dosages) may substantially lower fasting glucose in type 2 diabetic patients.⁴⁶⁸ While the mechanism remains unclear, it may be due to the enhancement of the biotin-dependent enzyme, pyruvate carboxylase, and its effect on utilization of glucose in the citric acid cycle.

Conjugated linoleic acid. Conjugated linoleic acid (CLA) is a mixture of isomers of linoleic acid and is found naturally in dairy products and meats. *In vitro* models using CLA have shown effects on peroxisome proliferators (PP) similar to those seen with the class of oral insulin-sensitizing agents known as thiazolidinediones.^{469,470} PPs exert their biological responses as the result of activation of a subgroup of nuclear steroid hormone receptors known as peroxisome proliferator activated receptors (PPARs). PPARs appear to modulate lipid and insulin metabolism through a variety of mechanisms, including regulation of gene expression and an increase in the mobilization and production of GLUTs. The PPAR agonist drugs, classed as thiazolidinediones, have been shown to decrease circulating glucose levels and also reverse insulin resistance.⁴⁷¹ CLA has been

shown in animal studies to share some functional similarities to these thiazolidinediones, and has further been shown to normalize impaired glucose tolerance and improve hyperinsulinemia.⁴⁷² However, clinical human research has been inconclusive.

Alpha-lipoic acid. Animal and human studies suggest that alpha-lipoic acid (ALA) increases insulin-stimulated glucose disposal. The mechanisms of action may involve improvement of glucose transport, an increase in the number or activation of glucose transporter proteins, or an increase in non-oxidative or oxidative glucose disposal.^{473,474,475,476} Recent human trials suggest that oral administration of ALA (600–1800 mg/day for four weeks) can improve insulin sensitivity in patients with type 2 diabetes.⁴⁷⁷ Additionally, a number of trials have also been conducted using ALA in the treatment of diabetic polyneuropathy (DPN) with doses of at least 600 mg per day. Results generally demonstrate that ALA improves this condition and support the assumption that ALA might exert some of its beneficial effects unassociated with glucose disposal. One hypothesis suggests that its effects in DPN are at least partially due to improved microcirculation.⁴⁷⁸

Green tea. Green tea may have important effects on insulin modulation. Primary phytonutrients in green tea are the catechins and epicatechins. *In vitro* and animal studies have shown catechins to be an insulin sensitizer, pancreatic protectant, helpful in the delay of glucose absorption, and able to repress hepatic glucose production.^{479,480,481,482,483} While the dosage for humans is not clear, doses of 200–400 mg/day of catechins have been used in various studies in other areas and appear to be very safe.

Cinnamon. Work on cinnamon began a few years ago with *in vitro* data that suggested this common spice had bioactive compounds that might have insulin-like effects.⁴⁸⁴ Other *in vitro* work appeared to confirm this.^{485,486} Follow-up animal experiments suggest that long-term use of cinnamon bark might provide benefit against diabetic complications.⁴⁸⁷ Recently, the first human clinical trial was published. In this placebo-controlled study, diabetic subjects given as little as 1 g/day of cinnamon powder for six weeks showed improvements in fasting glucose, triglycerides, LDL and total cholesterol.⁴⁸⁸

Summary

IRS is a complex disorder that requires a multifaceted plan to manage. With estimates that over a quarter of the United States population may already have signs and symptoms suggestive of this dysfunction, relying primarily on a pharmacological approach after a frank disease such as diabetes or heart disease has been diagnosed seems far too costly and unlikely to stem the rising tide. A primary prevention and early treatment strategy should be to maintain a healthy balance between glucose and insulin throughout each person's life by focusing on diet, nutritional supplementation, exercise, and other lifestyle modifications.

Perimenopause, Menopause, and Women's Health: The Dance of the Hormones, Part II Bethany Hays, MD

Introduction

The job of the clinician is to translate the scientific information obtained from various sources into a systematic evaluation and treatment plan for patients with specific or general complaints, or for patients who simply wish to stay healthy and enjoy a long life. Such an evaluation and treatment plan can be created in the area of female hormone therapies, despite the current fluctuations in the standard of care and the rapidly changing stream of information, by using the concepts of functional medicine.

A Clinical Approach

Although many clinicians are trained using a “protocol” approach, patient-centered care has more recently come to the forefront. Recognizing that treating individuals rather than the mean of a group (the bell-shaped curve) is a cornerstone of functional medicine.

Assessing Body Type

The first step in the assessment of the individual patient is to take a history and conduct a physical exam. Functional medicine—and the matrix (Chapter 34)—present a wonderfully coherent way to receive and organize the information uncovered in this process.

Physical examination of patients starts when you first set eyes on them:

- Look at body size and shape (weight distribution).
- Assess skin color, temperature, and tone. Is the hand trembling or sweating when you shake it?
- Notice any visible rashes or evidence of dry skin.
- Note posture, demeanor, and movement.

Although an initial evaluation should never be done with the preconceived idea of focusing on a specific part of the functional medicine web, when the clinician finds a preponderance of clinical issues in the neuroendocrine part of the web, he/she should start the evaluation of the patient by noticing size and weight distribution. Diana Schwarzbein describes the body habitus of people with dominance of the three major hormones.⁴⁸⁹

1. **Adrenaline or Catecholamine**—Members of this group are thin, with muscle wasting in any muscles they are not specifically exercising. Fortunately, many of them are exercising; unfortunately, the purpose of their exercise and other lifestyle activities is to stay thin. Many are overexercising, with a concomitant elevation in adrenaline levels. Ironically, even in the context of increased exercise, they lose muscle mass secondary to the metabolic effects of increased adrenaline levels. The marathon runner is the prototypical adrenaline body type.
2. **Cortisol**—Members of this group usually move to a high cortisol neuroendocrine pattern after years of living a high-stress, high-adrenaline/catecholamine lifestyle. With elevated cortisol comes a new fat distribution around the midsection. Contrary to popular belief, the apple body shape is less likely to be an indication of high insulin and more likely to be a sign of high cortisol. After many years of high cortisol output, they may progress to a cortisol deficiency state with relative inability to respond adequately to intercurrent stresses. Allergy, as an expression of relative adrenal exhaustion, can become a major component of their symptomatology with accompanying “allergic shiners.” Inflammatory symptoms also occur due to the inability to provide adequate cortisol response. If they have maintained an exercise program, they may not manifest the final step—insulin resistance.
3. **Insulin**—Members of this group are the insulin-resistant, and/or diabetic patients. They often put

weight on everywhere. They get there one of two ways: through a high cortisol lifestyle or through dysfunctional genetics. The former will have the apple body shape of their previous high cortisol and the latter may not. In the unusual case, a client can present with insulin resistance with a thin body habitus, so be cautious!

Since there are many factors active in the production and distribution of fat and muscle mass, this approach is not completely accurate, but it is surprising how often the body-type assessment is a useful finding in setting the course for further assessment.

Patient-centered History

After the initial assessment, the clinician should take a thorough history. (Chapter 34 provides an in-depth review of the overall patient assessment process.) Allowing patients to tell their stories, without interruption if possible, can be a valuable tool for the functional medicine practitioner. Most patients have never had an opportunity to do this without significant interruption. *Engaged listening* can create a context of safety for deeper revelations by the patient about their observations and fears related to their own bodies. (Chapter 36 explores the doctor-patient relationship in detail.)

While taking the history, the clinician should look for symptoms that suggest imbalances in major or minor hormones. A thorough **menstrual history**, including onset, frequency, length, volume, and character of flow in the past and recently, is important for the clinician assessing hormones. Other key indicators to look for include:

1. Evidence of estrogen dominance

- Breast tenderness
- Fibrocystic changes
- Heavy periods
- Fat distribution in the hips or thighs
- Anxiety
- Recent growth of fibroids
- Presence of endometriosis or symptoms suggestive of it, such as pain or dysmenorrhea

2. Lack of progesterone or imbalance between estrogen and progesterone

- Spotting before and after the period
- Anxiety
- Oral contraceptive use
- Hormone replacement of estrogen only

- Perimenopause
 - Oligo-ovulation such as in PCOS
- 3. Signs of perimenopause and menopause**
- Irregularity in menstrual cycle
 - Changes in length and flow of menstrual cycle
 - Increasing PMS symptoms
 - For postmenopausal women—when did they go through menopause; was it natural or surgical?
- 4. Whether the patient has had a tubal ligation or hysterectomy with or without removal of the ovaries.** Both of these procedures can affect ovarian steroid output, either temporarily or permanently, often without the patient knowing (since the uterus is absent). Many women have been started on hormone replacement therapy before they were truly menopausal and need to be tested to confirm their true status.

A **pregnancy history** should pay attention to size of infants, complications during pregnancy, any history of infertility and how it was managed, and what kinds of problems the children are having. (A major source of stress for mothers, with accompanying neuroendocrine imbalances, is the health of their children; some functional medicine guidance about issues such as family nutrition can make huge difference in the patient's life.)

The clinician should also be looking for evidence of imbalance in other systems that affect or interact with the female hormone system:

- 1. Testosterone imbalance**
- Acne
 - Anger or aggressiveness
 - Changes in libido
 - Hair growth or loss and distribution
 - Loss of muscle mass
- 2. Thyroid dysfunction**
- Constipation
 - Low or loss of energy
 - Muscle pain or burning
 - Changes in skin or hair
 - Depression
 - Irregular bleeding
- 3. Neuroactive chemical imbalance**
- Depression
 - Anxiety
 - Hot flashes
 - ADD
 - Poor sleep

- 4. Elevated adrenaline**
- Heart palpitations
 - Anxiety
- 5. Inability to secrete adrenaline** when needed (dizziness upon standing up)
- 6. High cortisol**
- Frequent colds or infections
 - Difficulty losing abdominal weight
- 7. Inability to secrete cortisol** when needed
- Allergies
 - Inflammatory diseases
 - Autoimmune diseases
 - Any problem that has been treated with corticosteroids
- 8. Insulin resistance**
- Infections or poor wound healing
 - Brain fog
 - Difficulty losing weight
 - Carbohydrate cravings
 - Excessive weight gain in pregnancy, or
 - A large-for-gestational-age baby
- 9. Inflammatory conditions**
- Dysmenorrhea
 - A history of endometriosis
 - Skin rashes
 - Arthritis and other pain symptoms

Once a picture of the patient's "functional web" has been created from the history, we proceed to the physical examination. Since most patients who come with the idea that they are there to get help with hormonal problems need a gynecologic exam, the following will be familiar to the gynecologist but incomplete from a general medical practice point of view. (A more complete approach is discussed in Chapter 34.)

Physical Examination

Important things to look for relative to endocrine function include (but are not limited to):

- 1. Vital signs**
 - Height and weight
 - Especially palpitations or elevated pulse
 - Elevated BP
 - Orthostatic hypotension
- 2. Skin**
 - Turgor
 - Dryness
 - Rashes
 - Hair distribution

- Flushing or mottling
 - Acne
3. Thyroid
 - Enlargement
 - Loss of tissue
 - Evidence of autoimmune disease (gland consistency)
 - Tremor
 - Eye signs (e.g., exophthalmia, lid lag)
 4. Breast
 - Cysts
 - Masses
 - Fibrocystic changes
 - Tenderness
 - Discharge
 - Dimpling
 5. Abdominal exam
 - Abdominal obesity
 - Liver size
 - Presence of gas or constipation
 - Masses
 - Ascites
 6. Vaginal exam
 - Vulvovaginal atrophy
 - Amount and type of discharge
 7. Uterine exam
 - Fibroids
 - Increased size or boggy of the corpus
 - Fixation or evidence of adhesions
 8. Ovarian exam
 - Size
 - Symmetric cystic enlargement
 - Masses suggestive of endometriosis or cancer
 - Fixation or evidence of adhesions

The clinician should be looking for signs of imbalance of the major hormones (adrenaline, cortisol, and insulin), evidence of high or low estrogen effect, underproduction or overproduction (or more often overdosing) of progesterone, evidence of overproduction or effect of testosterone, hypothyroidism or less often hyperthyroidism, as well as any pathology.

Most of the other imbalances of the endocrine system will require laboratory evaluation to ferret out. However, by the end of the history and physical, the clinician should have a reasonably clear picture of the three major hormones, the estrogen effect, the balance between estrogen and progesterone, and the presence of excessive or inadequate testosterone.

Laboratory Evaluation

A good clinician should use both clinical evaluation and laboratory data to evaluate hormonal status. Although liberal use of laboratory evaluation can be reassuring, the idiosyncrasies of hormonal fluctuation and the limitations of laboratory testing can lead to excessive expense and unhelpful information. Therefore, the clinician must learn to use the patient's symptoms and responses to guide diagnosis and therapy.

Because of the current concerns about hormone therapy, a clinician should have a low threshold for obtaining laboratory documentation of the levels of hormone replacement once a stable regimen is established, assuring that the therapy and dosage are normalizing hormone levels and not creating non-physiologic levels.

Evaluating hormone levels is difficult at best. Which test? Which fluid(s)? When to test? Ideally, one would test the levels in the tissue of interest; however, this is not yet clinically feasible in most instances. **It is important to remember that hormone levels in various target body tissues are likely to be very different than in the body fluids tested (blood, urine, or saliva).**⁴⁹⁰

Breast tissue for instance, especially in the area surrounding tumors, has been shown to elaborate aromatase, 17-OH-ase, and sulfatase, sometimes significantly increasing the local level of estrogens.

In addition to the absolute values of various hormones, it is important to assess the ratios of hormones that interact with each other, such as estrogen and progesterone, bound and unbound estrogen and testosterone, and 2/16-OH estrogen metabolites.

Because of the normal fluctuations of these hormones, it may be necessary to obtain multiple samples in order to average the levels over time and get an accurate picture. This is especially true premenopausally when there are dramatic fluctuations over the course of a single menstrual cycle. When evaluating multiple samples over the course of a menstrual cycle, it is most practical to obtain salivary hormone levels so that patients can do home collection of samples every few days over the course of a month. Because there is less fluctuation of testosterone over the month (except during mid-cycle), a single testosterone level during the month is usually adequate. This type of collection over the course of a month can be helpful to assess presence of ovulation, luteal phase deficiency (helpful in fertility patients and with certain types of menstrual abnormalities), and

ratios of estrogen to progesterone that can be compared with standards.

Single salivary hormone levels can be more problematic. Although single salivary estrogen levels appear to be reliable, there is considerable debate about the interpretation of salivary progesterone levels^{491,492,493,494} and testosterone levels.⁴⁹⁵ In particular, there has been controversy about the effectiveness of transdermal progesterone in protecting the endometrium and bone, and in the appropriateness of using salivary hormone levels to monitor progesterone transdermal therapy. It is clear that salivary progesterone, while reported to reflect the levels in serum, is much higher in saliva when administered transdermally than when given by mouth. The explanation for this has been that progesterone in transdermal creams is lipophilic and is absorbed by red blood cells in the capillaries, keeping serum levels low while delivering higher doses to tissues. A study by Lewis et al.⁴⁹⁶ using 20 and 40 mg doses of progesterone transdermally showed elevated and variable salivary hormone levels and no increase in RBC membrane levels of progesterone. In addition, despite high levels of progesterone in salivary secretions, most studies show failure of secretory changes in the endometrium with transdermal progesterone regimens,⁴⁹⁷ suggesting that levels may differ from one tissue to another. It should be noted, however, that in spite of this failure to induce secretory changes, the levels of progesterone reaching the endometrium appear to be able to prevent endometrial hyperplasia, the goal of most postmenopausal progesterone therapies.⁴⁹⁸

Urinary hormone levels over 24 hours allow an average level of hormone to be determined and the 2- to 16-OH estrogen ratio can be determined. Collection can be done at home, but is somewhat cumbersome for patients and must be compared to creatinine excretion to insure adequacy of collection.

Serum hormone levels correlate with perhaps the largest number of reported studies, and, in addition, serum hormone levels are more likely to be covered by insurance companies (with the right diagnostic codes). They are limited by providing only a “snapshot” of the often fluctuating hormonal milieu. As stated before, serum hormone levels do not necessarily reflect the levels in target tissues and therefore reflect availability of hormone precursors perhaps more than they reflect hormone effect.

In summary, because of complicating variables such as the difference between blood and tissue levels of hormone, and because of the biological effect of metabolites, xenoestrogens, and nutritional estrogens, the relevance of the measured hormone levels should be assessed with some degree of circumspection. The clinician will have to determine by experience which laboratory assessments to use in a given clinical picture (serum in single sample postmenopausal women whose hormones are relatively stable vs. multi-sample salivary collections in premenopausal women for the purposes of documenting ovulation or perhaps assessing hormone balance). In order to evaluate hormonal balance, hormone load, and free hormone levels, ordering serum testosterone, progesterone, 2- and 16-OH estrogens, and SHBG, all collected at the same time, will prove useful. The clinician should try several of these approaches and familiarize him/herself with an approach that seems to correlate best with the patient's symptoms and needs.

Prescribing Hormones

When prescribing hormones in my clinical practice, I am guided by the following principles:

1. Replace human hormones with bioidentical hormones.
2. Attempt to return hormone levels to “normal” physiological levels.
3. Attempt to give the hormone in the most physiological way.
4. Remember to consider other hormones that may affect the level of the hormone you wish to treat.
5. Check hormone levels by laboratory testing, if possible, to be sure you are creating normal levels.
6. Whenever possible, check downstream metabolites of administered hormones and hormones whose levels may be affected by the therapy.

Although it has been suggested that there is no evidence to prefer bioidentical hormones,⁴⁹⁹ it is clear that laboratory evaluation of hormone therapy requires that the hormones that are given and their metabolites be measurable with the clinically available laboratory tests. This cannot be done for conjugated estrogens or the commonly used progestins. The need to be able to evaluate levels of administered hormone is particularly important given the unstable medical-legal environment relating to hormone replacement therapy in menopause. In addition, the estrogens most frequently used in the

U.S. (conjugated equine estrogens) have a substantially different metabolism due to the large fraction of equine estrogens and the fact that because of the unsaturated B ring they are metabolized to DNA-damaging quinines.^{500,501} Some metabolites of equine estrogens are stronger estrogens than their substrate.⁵⁰²

Philosophically, one would think that the path of evolution would be more reliable than the rather brief history of human intervention, so whenever possible one should try to return hormone levels to established norms for age and gender. In order to achieve the integration of these goals into practice, the following questions should be asked and (hopefully) answered prior to initiating therapy:

1. Is the gland over- or, more often, underproducing the hormone?
2. If so, is it because it is “broken” (absent or affected by autoimmune disease)?
3. If it is not “broken,” is it compensating for another hormone that is abnormally low or high?

For example, it is conceivable that when adrenaline is high, thyroid will compensate to protect the heart from arrhythmias and excessive pulse rates. In this environment, administering thyroid hormone may put the heart under further stress. Without understanding this reciprocal relationship, many clinicians have had the experience of treating patients with symptoms of borderline hypothyroidism and slightly elevated TSH levels with a trial of thyroid hormone. The patient would return complaining that the cardiac and nervous symptoms were too much to handle. It is possible that these patients’ low thyroid function was balancing their high adrenaline state. Attempts to “normalize” their thyroid levels failed because the intervention (thyroid replacement) inadequately assessed the total metabolic picture. Thus, basing treatment of thyroid on a clinical parameter such as low basal body temperature without consideration of the complex mix and interaction of hormones can lead to further loss of hormone flexibility. Therefore, in the appropriate clinical context, it might be advisable to address the high adrenaline (catecholamine) levels with diet, lifestyle, and supplement approaches before treating borderline hypothyroidism with thyroxine or triiodothyronine.

In menopause management, there are currently two competing philosophies: one position suggests that premenopausal women are normal and postmenopausal

women are hormone deficient. The other says that premenopausal women are hormone toxic in order to have babies and postmenopausal women are normal. Depending upon which philosophy the clinician adheres to, he/she will treat postmenopausal women differently. In the first instance, the clinician will wish to return postmenopausal hormone levels to “normal” premenopausal levels; in the second, he/she will try to normalize women at a postmenopausal level of hormones. This author is an advocate of the second philosophy.

Since the WHI, there has been a growing discussion in the gynecological literature suggesting that if women are given low-dose hormone replacement they will not need progesterone therapy even if they retain their uteruses.⁵⁰³ This suggests that if postmenopausal women are only replaced to a level at the lower end of the range for normal menopause (10–40 pg/mL⁵⁰⁴), normal progesterone levels produced by the adrenal glands could provide enough balance to prevent endometrial hyperplasia,⁵⁰⁵ as they appear to do in unsupplemented women who maintain normal levels of hormone. If, however, adrenal progesterone (the primary source of progesterone after menopause) is being shifted instead into the production of cortisol (e.g., secondary to a stress-prone lifestyle), progesterone will need to be replaced to balance estrogen in various organ systems including breast, brain, bone, and uterus. This may also be true of women who have elevated estrogen levels due to obesity or inadequate metabolism and excretion of estrogens. These women are currently not being evaluated in any specific way and may be the true at-risk population. It is the author’s suspicion that, at physiologic levels, continuous progesterone HRT will not produce insulin resistance (a potential side effect of continuous progesterone HRT), obviating the need for cycling progesterone as has been recommended by some.⁵⁰⁶ However, since there are no randomized studies with this approach, careful monitoring of hormone levels and endometrial assessment with periodic biopsy or ultrasound should be done. Fasting insulin levels to assess the effects of progesterone on glucose metabolism would also be advisable.

Exogenously administered hormones are metabolized into “downstream” metabolites depending on

- the genetics of the CYP and phase II enzymes,
- the environmental up- and downregulators of those enzymes,

- dosage of hormone given, and
- whether the hormones are synthetic derivatives or bioidentical.

It is wise, therefore, to evaluate the downstream metabolites, as well as the hormone being administered, whenever possible. An example would be to obtain 2- and 16-OH estrogen levels before and after administering exogenous estrogen. Another would be to obtain estrogen and testosterone levels when administering pregnenolone or DHEA. Because enzyme function is often bi-directional, high doses of a hormone may flow upstream to precursors; for instance, estriol (especially when administered by mouth) has the potential to be converted to 16-OH estradiol, a much stronger estrogen.⁵⁰⁷ The author cannot report having seen this effect with vaginally administered estriol and has inadequate experience with orally administered estriol. When evaluating the “estrogen pool,” or the totality of estrogen receptor agonists, evaluation of SHBG can be useful, as it appears that levels of SHBG increase in response to many of the downstream metabolites, as well as to estrogen, estrone, and testosterone.

Balancing Hormones after Menopause

Ultimately-the role of hormone replacement is to replace or re-balance (a much more complicated prospect) missing or underproduced hormones. Since the various hormones interact with each other, it is important to try to understand whether a hormone is missing or is low because it is compensating for another hormone that is elevated or depressed.

It should also be remembered that normal levels of estrogen in postmenopausal women decline from around 30 pg/mL soon after menopause to as low as 5 pg/mL in later years. Women with undetectable levels of estrogen, however, were found to have increased risk of osteoporosis.⁵⁰⁸ Although levels in the range of 8 pg/mL were not shown to increase the risk of endometrial cancer,⁵⁰⁹ the higher the level of estrogen, the more likely endometrial hyperplasia is to occur unless opposing progesterone is given. Presumably, in women with low (normal) levels of estrogen, the progesterone balance is supplied by adrenal progesterone. Therefore, it might be assumed that women under stress might also be imbalanced with regard to progesterone and at higher risk for endometrial hyperplasia.

If estrogens are replaced, the level of balancing progesterone should be evaluated. If endogenous progesterone levels are low or endogenous estrogens are high, progesterone should be replaced or adrenal stress minimized to get endogenous levels back to a point of balance. When progesterone is administered vaginally, higher levels are found in the endometrium than in serum,⁵¹⁰ which may be important since both transdermal and transvaginal progesterone administration have been shown not to produce serum levels consistent with luteal phase. As stated previously, that does not necessarily mean that the patient is susceptible to endometrial hyperplasia or cancer. It also appears that luteal phase levels are not necessary if estrogens are replaced at low postmenopausal levels.⁵¹¹ Remember, the goal is to *normalize* hormone levels. It is important to remember that after menopause estrogens come primarily from peripheral sites that may be preserved even in the absence of ovarian tissue. Testosterone comes from both the adrenals and the ovaries, about 50% from each, and may need to be replaced, especially in the case of oophorectomy. Progesterone comes primarily from the adrenals and levels can be depressed when there is a high demand for cortisol such as with stress,⁵¹² allergy,⁵¹³ or inflammatory processes.

It is clear from the work of Hlatky, using the HERS trial data⁵¹⁴ and reconfirmed in the WHI,⁵¹⁵ that the majority (approximately 80%) of postmenopausal women do better without any hormone replacement. There are only a small number of women who will need HRT, and these are likely to be women with underfunctioning ovaries either from surgical removal, autoimmune destruction, or perhaps compensation for prolonged elevated levels of other hormones such as adrenaline; underlying imbalances of other hormones can be addressed with diet and lifestyle changes. The latter make up a significant percentage of the women who have undergone natural menopause but are complaining of hot flashes, insomnia, and anxiety/depression.

Estrogen administration. The most important symptoms that lead a woman or her practitioner to consider HRT are hot flashes,⁵¹⁶ insomnia,⁵¹⁷ and depression or anxiety.⁵¹⁸ Since these are all primarily brain symptoms, it is important to note that the brain is an ER- β rich organ. It would take much higher doses of estrone or estriol to engage these brain receptors and it is likely that they would have to be converted to estradiol to be effective. Nutritional phytoestrogens such as genistein

and coumestrol, on the other hand, might have a beneficial effect.^{519,520} This thinking has led the author to turn away from HRT containing estrone and estriol as the primary treatment for brain symptoms. The goal is to get the best, targeted effect while giving the smallest number of estrogen-like molecules, in the event that metabolism or excretion is not ideal.⁵²¹ Remember, it takes very few estradiol molecules to have a powerful effect. Although estradiol engages both the α - and β -receptors and therefore would be expected to have effects in the endometrium and breast (where growth stimulation would not be desirable after menopause), smaller doses are in the long run more physiologic and, if properly balanced with progesterone and perhaps testosterone, appear to be relatively safe.

Since the route of administration is clearly important, both in obtaining adequate blood and (brain) tissue levels and in the liver effects of these hormones, the most physiologic way to give HRT is via a route that does not produce first-pass effects in the liver. Transdermal estradiol is now readily available in commercial preparations of gels and patches. Transvaginal routes also appear effective. Although there would be a concern regarding higher levels of estrogen in the uterus when giving transvaginal estrogen, the higher uterine levels of vaginally administered progesterone, on the other hand, would be expected to be advantageous. Other routes, such as injectable and subdermal pellets, are also available, but are not as acceptable to patients or as easily managed by the practitioner. Buccal estrogens via troches are available from formulating pharmacies but provide a mixture of transmembrane and gut-absorbed hormone, and thus might be expected to have increased liver first-pass effects.

Since absorption from many of these routes varies from woman to woman, dosages should be started at low levels and titrated to the normal range. Patient symptoms can be used to determine that treatment effects are in the normal range (minimal hot flashes without insomnia and **no** breast tenderness or bleeding). Following normalization of symptoms, hormone levels can be obtained.

Progesterone administration. Progesterone can be administered with commercially prepared and tested oral and transvaginal formulations, and formulating pharmacies will make transdermal, buccal, oral or transvaginal preparations. Commercially prepared transdermal creams are also available with varying

amounts of USP progesterone per ounce. Levels obtained via any of these routes are highly variable due to differences in dose, absorption, and metabolism. When using progesterone primarily to protect the endometrium, rather than to support cortisol production or suppress anxiety, the vaginal route has the advantage of providing high local levels of progesterone without increasing serum levels appreciably.⁵²² Oral progesterone will in general have better effects on brain symptoms of anxiety because of its first pass through the liver, with subsequent production of allopregnanolone, a natural anxiolytic. While not strictly following the rule of normalizing hormones, this strategy may be temporarily helpful in women with anxiety. Women with very low cortisol output will sometimes respond to progesterone in higher doses due to progesterone's position as a cortisol precursor in the hormonal cascade. Transdermal preparations can be used and, if adequate blood levels are obtained, avoid the sedative effect of allopregnanolone in the brain. (The clinician should be aware of the potential connection between higher cortisol levels and worsening depression.)

Once symptoms suggest appropriate levels and a balance between estrogen and progesterone, levels should be obtained to determine that physiological values have actually been attained. Estradiol levels in the 15–25 pg/dl range, with adequate progesterone (greater than 0.3 ng/mL—1 ng/dL), are reasonable in the years immediately following menopause, provided there are no symptoms of hormone excess such as bleeding or breast tenderness. These levels represent early menopause to low follicular phase levels. They have been chosen somewhat arbitrarily since “normal levels” are usually obtained by measuring hormone levels in populations that have not been screened for the kinds of subtle mediating systems addressed in functional medicine such as adrenal stress, autoimmune destruction of the ovary, and testosterone and SHBG imbalances.

It is advisable to obtain informed consent with all HRT patients. On the type of regimes described above, patients should know that, while their risk of breast cancer is higher on any hormone replacement, their quality and length of life will be better if their hormones are balanced. If a patient is diagnosed with breast cancer while on hormone replacement, the clinician may be legally at risk if he or she cannot document such consent.

Replacing hormones after oophorectomy. In what appears to be an oversight of gargantuan proportions,

women who have undergone removal of the ovaries (approximately 50–60% of all women undergoing hysterectomy, or 300,000 per year^{523,524}) are often treated as simply postmenopausal. The incidence of hot flashes in these women is almost three-fold higher.⁵²⁵ These premenopausal women lose estrogen, progesterone, and testosterone production compared to “normal” menopausal women. They are also likely to be much younger and have potentially higher needs for these hormones. Physicians may be unaware of the differences between the normal postmenopausal woman and the surgically-induced menopausal woman; they are often lumped together in studies. Differences between these groups were noted in the literature as early as the 1930s when a Mayo Clinic study showed that the most severe atherosclerotic disease was not found in men but in women who had been ovariectomized.⁵²⁶

It is important to note that many of the studies on animal models that contributed to the early powerful bias that hormone replacement was **healthy** after menopause were done on spayed animals, which were then replaced with estrogen and/or other combinations of hormones. It is also important to note that these animals were likely to have less genetic diversity than that seen in the American human population and therefore, at best, would represent only a subpopulation of women at risk. Finally, true to expectation, when the women in the hysterectomized arm of the WHI were analyzed, a lower incidence of breast cancer was found. This was predicted, not because there were no progestins used, but because the estradiol levels in the patients in that study would be expected to be lower, since a standardized dosage of .625 mg of conjugated equine estrogen (CEE) was given in both arms of the study. This translates to a total higher level of estrogen in the non-hysterectomized, postmenopausal women arm of WHI. Indeed, the hysterectomized ERT group had a RR of breast cancer of .77 (CI 0.59–1.01), while the risk of breast cancer in the non-hysterectomized group was 1.26 (CI 1.00–1.59).^{527,528}

These findings do not prove that estrogen is safe to give without progestin; they simply indicate that normal-to-low levels of estrogen carry a lower risk of breast cancer than higher-than-physiologic levels do. And these findings do lead us to a rational approach for women who have had hysterectomy, with or without oophorectomy. The goal should be to normalize hormone levels. For women below the age of 50, normal

follicular levels of 20 pg/mL to perhaps as high as 60 pg/mL should suffice. Cycling with progesterone in the luteal phase of the cycle is appropriate in the higher ranges and is less likely to lead to insulin resistance than continuous therapy.⁵²⁹ These relatively lower levels of hormone may still yield higher numbers of breast cancer than had hormone not been replaced, but leaving these women in a sub-physiologic range will increase their overall morbidity and mortality. Their risk compared to normally menopausal women should be reduced.

Around age 50 and approximately every 10 years or so thereafter, hysterectomized women should be re-evaluated with serum estradiol levels, and hormone replacement should be normalized to postmenopausal levels at their newly achieved age. ERT is usually not necessary after the age of normal menopause, if estradiol levels are maintained by fat production. If this is not the case, however, ERT should be given transdermally. Progesterone will also need to be normalized in order to balance brain effects of estrogen. If brain symptoms are not a problem, estrogen alone should be given until further information is available about bio-identical progesterone in the menopause. There is inadequate support at this time to say that natural progesterone—even in high doses—supports bone growth or prevention of osteoporosis,^{530,531} although physiologically this is possible. If the woman is under stress, her progesterone levels are likely to be low and she will need replacement to normalize levels. In these women, bone loss will be greater, so care should be taken to attend to normalizing hormones and using nutritional support to prevent osteoporosis.

When oophorectomy has been performed, it is important to remember that a significant drop in testosterone will occur. This is likely to cause further endocrine imbalances by increasing SHBG and binding more free estrogens and the testosterone that is available from the adrenals. Although normalizing testosterone levels has been shown to improve libido in postmenopausal women, it is not a panacea for loss of libido at midlife.

Use of estriol. Estriol has been used both orally and transvaginally with the assumption that because of its lower estrogen receptor affinity, it would be safer. Data from a case-control study in Sweden,⁵³² where many women have been prescribed both vaginal and oral estriol, showed an increased incidence of endometrial cancer in women taking oral estriol in doses of 1–2 mg, OR 2.0 (1.6–2.6), but no statistically significant differ-

ence in women taking the vaginal preparations of estriol or dienestrol, OR 1.2 (1.0–1.6). In this study, endometrial cancers were more likely to be lower grade and less invasive in women using estriol orally. However, there was no difference in those using vaginally delivered estriol, supporting the lack of connection to the vaginally administered hormone. Previous studies have shown that estriol in 6 mg oral doses can produce vaginal bleeding when progestins are added.⁵³³ Studies have also shown that lower doses produce decreased symptoms and prevention of bone loss.⁵³⁴

Oral estriol is metabolized in the liver by conjugation, but is not well bound to SHBG or albumin in serum. Therefore, levels of free, biologically active estriol are significant and can lead to estrogen effects. There is also concern that orally administered estriol might be processed in a “retrograde” fashion to the much stronger 16-OH estrogens of which it is a downstream product in normal estrogen metabolism. This has not been demonstrated clinically. Vaginal estriol is much more readily absorbed; 1 mg of vaginal estriol and 10 mg of orally administered estriol appear to have similar effects. However, much lower doses of estriol are normally administered (1–2 mg orally and .5 mg twice weekly vaginally are standard doses in the Swedish study cited above). Furthermore, as the vaginal epithelium cornifies under the influence of estriol following 1–2 weeks of therapy, less of the drug is absorbed.⁵³⁵ Vaginal estriol appears to be both safe and effective for urogenital symptoms.⁵³⁶

Studies suggest that vaginally administered estriol (.5 mg daily for 2–3 weeks then twice weekly) is effective in the treatment of atrophic vaginitis with minimal if any effect on the endometrium. Orally administered estriol in a daily dose of 1–2 mg is more problematic and should be considered potentially hazardous to the endometrium and possibly the breast. Occasionally, women will complain of increased hot flashes that are presumably caused by the antiestrogen SERM effect of estriol. I have also seen resolution of hot flashes, confirming the individually diverse nature of estriol metabolism.

Recently, a murine model of MS has shown potential benefit from estriol,⁵³⁷ suggesting that it may be useful in autoimmune diseases. Further work will be necessary before applying this information to humans.

Replacing testosterone. Testosterone has many important functions in balancing the hormonal effects of estrogen. Testosterone has numerous effects on

estrogen availability and effect. Increased testosterone decreases sex hormone binding globulin (SHBG), making both estrogen and testosterone more available to the tissues. In women who are at risk for estrogen-related tumors, or who have a tendency toward anxiety and irritability (PMS), these effects can be undesirable. It is important to note, however, that the correct level of testosterone must be maintained around .4 ng/mL.⁵³⁸ When giving testosterone to women, very small doses may be adequate. Higher doses will have a negative effect on lipids, and possibly vascular compliance, as well as producing unpleasant side effects such as acne and hair loss.

There is evidence that women with higher levels of testosterone have a higher risk of breast cancer.⁵³⁹ This report referred to endogenous testosterone and therefore may represent metabolic uniqueness (such as the effect of insulin on CYP 17,20 lyase in the population of women with insulin resistance—a known risk for breast and uterine cancer). Testosterone has also been shown to decrease the proliferation of mammary epithelium in oophorectomized rhesus monkeys given estrogen by increasing the ratio of ER-beta to ER-alpha and lowering MYC oncogene expression, thereby exerting an anti-estrogen effect on the mammary epithelium. Once again, it is important to first measure the levels of hormones before administering exogenous hormones to postmenopausal women and then to monitor levels during treatment, as other hormone levels (such as insulin or androstenedione) might change with treatment, creating unintended effects.

Testosterone also has central effects, increasing vasopressin, which is associated with better ability to focus (its absence has been related to ADHD and chronic fatigue) and to libido, explaining some of the positive effects of testosterone in postmenopausal women.⁵⁴⁰

Genomics and Hormone Balance

When family history suggests a genetic pattern of disease, such as breast or ovarian cancer, genetic testing can be both explanatory and helpful in creating therapeutic interventions. A number of SNPs have been shown to have a relationship to the production and metabolism of hormones. As we become better able to identify these genetic polymorphisms in our patients, it is important to evaluate their usefulness in formulating interventions that address manipulation of hormone levels. In a recent study in the *Journal of the National Cancer Institute*, the

association between levels of sex hormones and SNPs for enzymes that regulate them was studied.⁵⁴¹ The results from this study suggested that only polymorphisms in the CYP19 aromatase enzyme and SHBG contributed to the variation in circulating hormone levels. (Remember that hormones in the serum do not reflect the local production of hormones.) Tumors of the breast in particular appear to be able to recruit available genes in the production of increased estrogen. This would seem more likely than that the cancer cell mutated to produce a gene that increased estrogen.

In another study,⁵⁴² multiple SNPs of interest to hormone metabolism were studied. Of these women, 66% had at least two homozygous mutant SNPs of interest. A thrombophilic pre-disposition was found in 9.9% of women, and 23% of women had at least two SNPs associated with an increased risk of breast cancer (COMT, CYP17, CYP19, CYP1A1, and CYP1B1). This would suggest that these women might be at increased risk from HRT such as was used in the WHI. The SNPs predisposing women to cardiovascular pathologies (e.g., APOE, AGT, eNOS, and PAI-1) were found in 12.3% of women. SNPs predisposing to early postmenopausal bone loss and osteoporosis (ER-alpha and VDR) were found in 26.7% of women. The authors conclude: "These data suggest that the assessment of SNPs associated with risks and benefits of estrogen/hormone therapy may be a new means to individualize counseling about and prescription of estrogen/hormone therapy in up to 66% of women." Work in this area has focused on the analysis of polymorphisms of potential functional significance in several classes of genes, including those involved in carcinogen metabolism, estrogen metabolite biosynthesis, steroid hormone receptor activation, and DNA damage response.⁵⁴³

Critical enzymes for which gene SNPs have been determined include (some of the tests are commercially available):

- **CYP1B1**—This cytochrome P450 detoxification enzyme in the liver is responsible for metabolizing a number of drugs and chemicals. When acting upon estrogen (and especially the estrogen-like horse hormones equilin and equilenin), this enzyme produces 4-OH estrogens,⁵⁴⁴ which are rapidly converted into quinones, which are adducts of DNA. SNPs that upregulate this enzyme can increase the production of cancer-causing 4-OH estrogens.^{545,546} Polycyclic aromatic hydrocarbons⁵⁴⁷ and tobacco smoke are biotransformed through this P450 enzyme, further upregulating it. DHEA, hesperetin (a flavonoid), and resveratrol have been shown to be downregulators of this enzyme. It should be noted that studies attempting to link CYP1B1 polymorphisms and breast cancer incidence have not shown a correlation with this enzyme by itself.^{548,549}
- **CYP1A1**—This enzyme is responsible for the production of 2-OH estrogens. Once methylated, these downstream metabolites are thought to be protective estrogens; the methoxylated form is currently being studied as a cancer therapy. There appear to be many variants of the CYP1A1 gene, each associated with different diseases. For instance, CYP1A1 4887A and 4889G may be precipitating factors for susceptibility to psoriatic arthritis; an additive effect was found between them.⁵⁵⁰ CYP1A1 6235C allele carriers showed a non-significant ($P=0.06$) trend towards a decreased risk of ER-positive breast cancers ($OR=0.65$, 95% CI 0.42–1.02), but not ER-negative breast cancers.⁵⁵¹ In a multiple model, CYP1A1-1 MspI restriction fragment length polymorphism (RFLP) T→C ($p=0.004$), and CYP1A1-2 Ile462Val A→G ($p=0.03$), were found to be associated with significantly decreased and increased risks of breast carcinoma, respectively.⁵⁵² These subtleties add significant value to the interpretation of an assay for limited SNPs.
- **CYP3A family**—Assays for these enzyme genes are not currently available to clinicians but are responsible for 16-OH estrogens. They can be upregulated by xenoestrogens such as those found in pesticides. They appear to be upregulated in obesity.
- **MTHFR (methyltetrahydrofolate reductase)** is responsible for activating folate to 5-methyltetrahydrofolate, one of the key steps in the production of methyl groups and in conversion of homocysteine to methionine. The 677C→T variant is seen in 20% of the population. Increased folate supplementation or providing the activated folate as 5-methyl or 5-formyl-tetrahydrofolate can compensate for this abnormality. Measuring homocysteine levels after therapy confirms the effectiveness of this therapy.
- **COMT (C-O-methyl transferase)** transfers the methyl group from methionine to many substrates in the body's metabolic processes. Persons who are homozygous positive for the M-alleles of this gene

- have four-fold reduction of COMT activity and are associated with slowed metabolism of dopamine, epinephrine, norepinephrine, and drugs like L-dopa.⁵⁵³ They may have decreased postsynaptic catecholamine receptors and an increased risk of certain neuropsychiatric illnesses such as rapid cycling bipolar disorder, antisocial behavior, violence and suicide in schizophrenics. Activity of this enzyme has been shown to be downregulated by catechol-containing phytonutrients such as quercetin, with a subsequent increase in DNA damage.⁵⁵⁴ However, a study by Wu et al. showed, among Asian women with lowered COMT activity, the decreased metabolism of catechins from green tea increased its antioxidant capability, thereby decreasing the incidence of breast cancer.⁵⁵⁵ Other alleles are also associated with increased risk of breast cancer.⁵⁵⁶ Activity of this enzyme may be improved by increasing the substrate methionine with SAME.
- **CYP19 aromatase** is responsible for converting adrenal androgens into the estrogens estrone and estradiol. Aromatase inhibitors have recently received a great deal of attention as cancer adjunctive therapy. The inflammatory prostaglandin E2 is a potent upregulator of CYP19⁵⁵⁷ and therefore COX-2 inhibitors such as omega-3 fatty acids or low-dose aspirin⁵⁵⁸ may be able to decrease aromatization of adrenal steroids to estrogens.
 - **CYP17 (17 α -hydroxylase/17,20-lyase)** converts 17-OH progesterone and 17-OH pregnenolone to androstenedione and testosterone. This enzyme is upregulated by insulin in insulin resistance syndromes and PCOS.
 - **EDH17 B2 (17 β -hydroxysteroid dehydrogenase type 2)** converts androstenedione to testosterone and estrone to estradiol. It has been found in breast tissue and fat and is responsible for the conversion of adrenal steroids to estrogen in these tissues.
 - **SHBG**—Two SNPs have been found that increase levels of SHBG. Since these are not available commercially, and since SHBG can be measured directly, it is important to remember that SHBG levels can be controlled genetically and not just in response to hormone levels.
 - **VDR**—Recurrent references to vitamin D receptors are encountered when reviewing the literature.^{559,560,561} Vitamin D appears to be important in apoptosis and therefore has an impact on epithelial cell cancers such as breast, prostate, and colon cancers. Vitamin D is also involved in immune cell apoptosis and therefore interacts with the inflammatory cells that respond to estrogen in diseases such as Th1 mediated autoimmune diseases^{562,563} and osteoporosis. The vitamin D receptor in rats and mice has been shown to be estrogen sensitive.⁵⁶⁴
 - **IL-1 β** —Upregulators of the promoter sequence (31C-T) increase IL-1 β , which has been shown to increase pituitary production of FSH and have an effect on LH production, which may be involved in the suppression of fertility during chronic disease.⁵⁶⁵
 - **IL-6 (–174 G-C)** is a Th2 cytokine upregulator that has also been shown to increase FSH and LH production.
 - **UGT (UDP-glucuronosyltransferase)** has been shown to have polymorphisms that can affect the levels of estrogen and testosterone in the circulation. Lowering hormone levels has been shown to increase the numbers of ER- and PR-negative cancers. Since these cancers have a worsened prognosis than the ER/PR-positive tumors, these polymorphisms might be important.
 - **SULT (Sulfotransferase)** has also been shown to have polymorphisms that affect hormone availability, thus affecting the risk of ER-positive tumors.⁵⁶⁶

Dietary Modifications to Decrease Diseases of Estrogen Metabolism

A diet aimed at decreasing estrogen production would be expected to lower the risk of breast and uterine cancer and decrease symptoms of Th1 autoimmunity. This diet can also be helpful in PMS and may improve fertility in women with overproduction of estrogen or an estrogen-dominant imbalance of estrogen and progesterone. Metabolic functions that are diet responsive include production of estrogen by aromatase, metabolism to 2-OH vs. 16-OH estrogens, phase II methylation, sulfation, and glucuronidation, enterohepatic circulation of excreted estrogens, and the presence of xenoestrogens and phytoestrogens in the food.

A diet aimed at maintaining normal body mass index would be expected to improve hormone function and decrease the risk of estrogen-related disorders. In patients susceptible to insulin resistance, the appropriate balance of protein and carbohydrate will be important. Eating *organically grown* foods, especially hormone-free

meats from animals known to concentrate xenoestrogens in the fat, would be expected to decrease exposure to xenoestrogen, as well as down-regulate CYP3A enzymes that produce 16-OH estrogens and inhibit 2-OH estrogens. Fatty acid precursors of inflammatory prostaglandins (arachidonate) concentrated in red meat, milk, and eggs, may increase PGE-2 and aromatase, so limiting these foods would be wise. Chapter 26 contains a very thorough and well-documented review of dietary influences on health, including those summarized briefly below.

Milk and Soy

Jane Plante has suggested that the epidemiology of milk drinking around the world, and the induction of high levels of IGF-1 in bGH-treated cows, make milk drinking problematic for some breast cancer patients.⁵⁶⁷ Milk drinking has also been shown to be problematic for women at risk for ovarian cancer.⁵⁶⁸ Substituting soy milk and adding other soy products appears to be a useful approach for many reasons and may be especially helpful for young women in preventing later cancers. Use of isoflavones not obtained from soy foods, especially in the menopause or in women who have breast cancer, is still controversial. However, accumulating data in humans appears to favor soy as a food substance in these situations, or at least to suggest they do not increase risk.

Vegetables

A diet high in cruciferous vegetables and, therefore, indole-3-carbinol would be expected to increase production of 2-OH estrogens, improving the 2-OH/16-OH ratio and lowering the estrogenic pressure in the system. Brightly colored vegetables and fruits containing antioxidants would be expected to decrease oxidative damage to DNA and to lower risks. Methylation is also important; since there are high numbers of MTHFR and COMT polymorphism carriers, a diet high in vegetables containing B vitamins would be prudent. Sulfate groups are supplied by garlic and onion and, for those able to process these foods, an advantage in sulfation of circulating estrogens could accrue.

Fiber and Fat

Rock and colleagues showed that a diet higher in fiber and lower in fat significantly decreased bioavailable estrogen.⁵⁶⁹ The effect was primarily mediated by

the fiber, which is thought to bind estrogen in the gut, preventing enterohepatic recirculation. Freshly ground organic flax seeds provide fiber, omega-6 and omega-3 precursors, and flax lignans. It is difficult to protect flax oil against oxidation and it does not reverse the common omega-3/omega-6 deficit.

Mozaffarian et al. showed that a diet high in *trans* fatty acids increased systemic inflammation in women in the Nurses Health Study.⁵⁷⁰ Diets high in omega-3 fatty acids, as would be expected, have been shown to have the reverse effect, so it appears that a prescription of “good fats” is preferable to one of “no fat.”

Sugar and Alcohol

A diet low in sugar and high in fiber would be expected to improve bacterial flora, further decreasing enterohepatic recirculation of estrogens by normalizing β -glucuronidase in the gut. D-glucarate, also found in colorful vegetables, has been shown to block glucuronidase activity and lower enterohepatic recirculation of estrogens.⁵⁷¹ Such a diet might also limit overgrowth of yeast with its concomitant mycoestrogens and alcohol production. Sad as it is to say, since we all seem to love sugar, a diet low in simple sugars appears to be appropriate for many reasons other than discouraging yeast growth. Sugar is the preferred substrate of cancer cells⁵⁷² and has profound effects in inducing insulin resistance. A diet low in sugar should be encouraged. Limiting alcohol to small amounts of resveratrol-containing wines (red) may help to normalize CYP enzymes affecting the ratios of 2-, 4-, and 16-OH estrogen metabolites.

Supplements

- **I3C** upregulates CYP1A1, increasing protective 2-OH estrogens,⁵⁷³ and may reduce 4-OH.⁵⁷⁴
- Some potentially useful COX-2 inhibitors and anti-inflammatory supplements include **omega-3 fatty acids, curcumin, hops, boswellia, rosemary.**^{575,576,577,578,579}
- **Curcumin** increases glutathione and induces GST.⁵⁸⁰ **It should not be used if the patient is on cancer chemotherapy.**
- *Vitex agnus-castus* may help to balance estrogen/progesterone in premenopausal women.^{581,582}
- **Silymarin** improves liver detoxification pathways.^{583,584}

- **Green tea extract** and quercetin should be avoided in COMT-deficient patients, but otherwise may be helpful.⁵⁸⁵
- **Dong quai** is used traditionally in combination with other herbs and these combinations have not been adequately studied. In a single trial by itself it was not effective for hot flashes.⁵⁸⁶
- **Amino acid supplements**, especially in those patients with decreased protein intake (some vegetarians) or absorption (hypochlorhydria), improve phase II detoxification, antioxidation, and brain function.^{587,588,589}
- **Activated folic acid**, B6, and B12 improve availability of methyl groups.^{590,591}
- **SAMe** provides the substrate for COMT.⁵⁹²
- **Isoflavones** from soy, or other plants such as kudzu, improve 2-OH/16-OH estrogen ratios;⁵⁹³ isoflavones from red clover and flax may act as SERMS. However, research is limited and results are mixed.⁵⁹⁴
- **Fiber and probiotics** improve gut excretion and gut flora, decreasing β -glucuronidase and its associated increased enterohepatic recirculation of estrogens and yeast overgrowth and the associated increase in mycoestrogens and ETOH production in the gut. See Chapters 28 and 31 for extensive information on gut function and flora.
- **Vitamin E** may inhibit the growth of breast cancer cells⁵⁹⁵ and prevent oxidation of cellular fats.⁵⁹⁶ There is limited research to suggest that vitamin E is effective against hot flashes.^{597,598} A recent double-blind study suggests it is effective for dysmenorrhea.⁵⁹⁹
- **Vitamin D** protects bone density⁶⁰⁰ and decreases risk of epithelial cancers such as prostate,⁶⁰¹ breast,⁶⁰² and colon.⁶⁰³
- **Calcium-D-glucarate** decreases β -glucuronidase and its associated increased enterohepatic recirculation of estrogens.^{604,605}
- **NaSO₄ and Glucosamine SO₄** make sulfate groups available to bind with estrogen in biotransformation phase II excretion.
- **Antioxidant supplements** containing the full spectrum of antioxidants prevent oxidative damage to DNA. Interestingly to functional medicine clinicians, a 2004 analysis of the research suggests the following: "Clinical studies mapping the effect of preventive antioxidants have shown surprisingly little or no effect on cancer incidence. The epidemi-

ological trials together with *in vitro* experiments suggest that the optimal approach is to reduce endogenous and exogenous sources of oxidative stress, rather than increase intake of antioxidants."^{606,607} **Some antioxidants should not be used during chemotherapy or radiation therapy as they may limit the effectiveness of therapy.**

Summary

The primary purpose of the therapies discussed here is to prolong life, preserve functionality, and maintain maximum flexibility in the (human) system. The approach to achieving these important goals is to normalize as many hormones as possible using lifestyle and dietary changes, as well as bioidentical hormones in doses and routes of administration that mimic, as far as possible, natural secretion of these hormones. As our understanding of genetics and the interaction of genes and environment improves, we will be able to modify the function of hormonally important enzymes, inducing changes that may be advantageous in improving fertility and longevity, and in reducing the symptoms of women in hormonal transitions.

Fibroids and Endometriosis

Joel M. Evans, MD

A comprehensive history and physical examination, as well as a detailed understanding of hormone metabolism, set the stage for the successful management of estrogen-related disorders. Two seemingly disparate diseases, fibroids and endometriosis, are currently erroneously classified solely as disorders of hormone metabolism. Actually, they fit into the functional medicine web, which recognizes the contribution of processes such as inflammation, detoxification, and blood sugar metabolism.

Fibroids (leiomyoma), which are benign smooth muscle neoplasms, and endometriosis, which is characterized by the presence of endometrial glands and stroma outside of the lining of the uterine cavity, are both disorders of estrogen-sensitive tissues. Thus, they share common treatment strategies, such as improving estrogen metabolism both directly and indirectly.

Fibroids

Fibroids are the most common pelvic tumor in women,⁶⁰⁸ occurring in up to 40% of women, with a higher incidence (up to 50%) in African American women.⁶⁰⁹ They can arise in any body tissue that contains smooth muscle, but they most commonly occur in the smooth muscle (myometrium) of the uterus. Though they can be solitary, they usually are found in multiple sites within the uterus and vary in size from microscopic to the size of a melon, or even larger. Because of the large degree of variation in number, size and location of fibroids, the intensity of symptoms varies from purely asymptomatic to severely disabling with many possible manifestations,⁶¹⁰ including:

- Abdominal and/or pelvic pressure
- Pain
- Abnormal bleeding (if located in or causing distortion of the uterine cavity)
- Urinary frequency
- Painful intercourse
- Increase in abdominal girth
- Fatigue due to anemia
- Urinary obstruction
- Infertility
- Pregnancy complications such as preterm labor, dysfunctional labor, and abnormal fetal presentations (breech and transverse lie)

Even with this long list of possible symptoms, the majority of women with fibroids have no symptoms, and they are discovered on routine pelvic exam or ultrasound.

The cause of fibroid tumors has not yet been precisely determined. They are believed to develop from a single cell. Because of observed familial associations, genetic determinants are believed to play a role.⁶¹¹ The current hypothesis is that leiomyomatous transformation is related to a mutation of a normal smooth muscle cell being influenced by estrogen, progesterone, and local growth factors. Once the smooth muscle cell undergoes leiomyomatous transformation, estrogen and progesterone receptors are found in higher concentration than in normal myometrium. Estrogen, progesterone, and growth factors are all likely involved in tumor growth, though the exact mechanisms are unclear.⁶¹²

The long-held belief in conventional gynecology that estrogen is the primary stimulus for fibroid growth is based on clinical observations:

- Fibroids are rarely found before menarche.
- Most shrink following surgical or natural menopause.
- Most enlarge during pregnancy.
- Some enlarge with oral contraceptive use.
- Most shrink with medications that reduce estrogen levels (e.g., aromatase inhibitors).

Based on these observations, the conventional pharmacologic approach has been to decrease ovarian estrogen production by inducing a “medical menopause” with gonadotropin-releasing hormone (GnRH) agonist therapy.⁶¹³ There are two main limitations of this approach. The first is that by inducing a rapid shift into a menopausal state, symptoms of ovarian hormone deficiency can be severe. More importantly, GnRH agonist therapy is not a long-term solution, as these medications can only be prescribed for a finite amount of time (3–6 months) and, following withdrawal of the medication, the fibroids usually return to their pretreatment size.⁶¹⁴ Thus, the main use of GnRH agonist therapy has evolved to that of a pre-surgical intervention in cases where the surgeon feels that some reduction in fibroid size is technically advantageous (although at least one recent study indicates that there may be no significant effect in intraoperative blood loss from such treatment⁶¹⁵).

The conventional gynecologic approach to fibroids that are asymptomatic (the majority of fibroids) is observation, which obviously does nothing to prevent further fibroid growth. Because observation does not address the functional imbalances that contribute to fibroid growth, many women ultimately require medical, surgical, or radiological treatments with the accompanying morbidity and even mortality associated with those approaches.

A functional approach to fibroids, therefore, first and foremost addresses asymptomatic fibroids with the objective of *preventing* future growth and *preventing* the development of symptomatology requiring medical or surgical intervention. Because of the association of estrogenic stimulation with fibroid growth, normalization of estrogen metabolism (both production and elim-

ination) is the major point of entry into the functional medicine web for the treatment of both symptomatic and asymptomatic fibroids.

Endometriosis

Endometriosis tissue, like the endometrium from which it is derived, is estrogen sensitive and is therefore associated with painful menses. Because the endometrial tissue is located in areas other than where it is supposed to be, a local inflammatory response is created that contributes to pain and to difficulty conceiving. It is for these reasons that conventional treatment prescribes oral contraceptives (which are progesterone dominant and have the effect of creating an inactive endometrium), and anti-inflammatory medications.⁶¹⁶ In severe cases, GNRH agonist therapy (designed to create a medical menopause to decrease estrogenic stimulation) or surgery is indicated. Before understanding the basis for a functional approach to treatment, it is important to realize that, unlike normal endometrial tissue, which responds only to circulating estrogen, endometriosis tissue contains aromatase⁶¹⁷ and produces, and is stimulated by, its own estrogen. The proinflammatory prostaglandin PGE₂ is the most potent stimulator of aromatase in endometriosis tissue,⁶¹⁸ making normalization of PGE₂ levels and reduction of inflammation a therapeutic priority on a par with maintaining normal estrogen levels.

Since fibroids and endometriosis tissue are both estrogen sensitive and both contain aromatase, which is upregulated by PGE₂, it is easy to see how treatment goals of normalizing estrogen metabolism and inflammation are similar for both conditions.

Treatment

Before it is possible to normalize estrogen metabolism, production, and elimination (a therapeutic goal), certain physiologic parameters must be assessed. In premenopausal women, salivary testing has been shown to accurately reflect serum levels of sex steroid hormones.⁶¹⁹ Salivary testing offers many advantages over serum testing. Non-invasive specimen collection, which is more convenient and less expensive, allows for the multiple collections necessary to evaluate diurnal and monthly cycles. Salivary testing also reflects the bio-available fraction of hormones, which is critically important because the bioavailable form (free hormone NOT bound to sex hormone binding globulin) is the biologically active

form. Since the fundamental therapeutic goal is the normalization of estrogen levels, a month-long profile will identify whether the background hormonal milieu is estrogen dominant, in which case more aggressive interventions to lower estrogen levels are required than when sex hormone levels are normal.

Since all estrogens in the body are synthesized from androgens via the enzyme aromatase, preventing stimulation of aromatase activity (which would therefore increase estrogen levels) *must* be the first step in the therapeutic strategy. Adipose tissue has aromatase activity,⁶²⁰ so the elimination of excess adipose tissue through the achievement of ideal body weight plays a major role in ensuring appropriate estrogen levels. Aromatase activity is stimulated by insulin, so normalization of insulin and glucose metabolism is critical (topic discussed previously in this chapter). Additionally, insulin decreases SHBG levels, which serves to further increase circulating levels of bioavailable estrogen to stimulate fibroid growth. Fibroid cells, in contrast to normal myometrium, contain aromatase,⁶²¹ further increasing the importance of controlling insulin levels. This is true for endometriosis tissue as well.⁶²² Interestingly, aromatase activity in fibroids and endometriosis tissue is stimulated by the proinflammatory prostaglandin PGE₂,^{623,624} making the reduction of inflammatory processes a critical goal. It is important to remember that overweight and obese women are often in an inflammatory state due to the many proinflammatory cytokines produced by adipose tissue.⁶²⁵ This serves to underscore the importance of achieving ideal body weight in women with estrogen-related disorders.

Other ways to decrease aromatase activity (and decrease estrogen levels locally and systemically) include the use of pharmacologic (anastrozole and letrozole) and natural (resveratrol,⁶²⁶ chrysin, soy,⁶²⁷ saw palmetto, and flax lignans⁶²⁸) aromatase inhibitors.

An additional lifestyle change that can help decrease estrogen levels is eating organic foods. The goal of eating organic is to decrease exposure to estrogens that are added to foods, and to pesticides that either stimulate aromatase (atrazine) or are converted in the body to estrogen-like substances (xenoestrogens).

The next step in assessing any patient with an estrogen-sensitive syndrome (e.g., fibroids and endometriosis) is to ensure estrogen is adequately eliminated from the body. This is done by assessing the body's detoxification system (where estrogen is eliminated through

the phase I and II detoxification pathways) and the health of the GI tract (where estrogen is dumped from the liver into the small intestine and dysbiosis can lead to increased beta glucuronidase levels that may increase enterohepatic recirculation of estrogen). (See Chapters 22 and 31 for in-depth discussions of detoxification.) Abnormalities of detoxification, digestion, and elimination (constipation), therefore, must be corrected if the body is to properly eliminate estrogen.

Another area of the functional medicine web that needs to be assessed and addressed is the relationship of the mind, body, and spirit. It is common knowledge, and a nearly universal experience of women and their caregivers, that stress can lead to irregular menstruation and amenorrhea through the disruption of hypothalamic and pituitary gland function, which can be associated with increased estrogen levels. Therefore, stress reduction, conflict resolution, and spiritual health are important to achieving not only hormonal regulation but also overall well-being.

It is important to note that the core functional medicine interventions to treat fibroids and endometriosis are not viewed by conventional gynecologists as treatments of choice. These interventions include:

- achieving ideal body weight (decreases aromatase and inflammation),
- eating organic foods (removing exogenous sources of estrogen-like compounds),
- reducing stress (optimizing pituitary function),
- optimizing insulin/glucose metabolism (decreasing stimulation of aromatase and normalizing levels of SHBG),
- decreasing inflammation (decreasing PGE₂ stimulation of aromatase), and
- normalizing detoxification, digestion, and elimination (ensuring adequate removal of estrogen from the body).

We believe that throughout this book, as well as in this particular chapter, analysis of the underlying science demonstrates that the physiology and biochemistry involved in estrogen-related disorders are of critical importance in developing treatment plans. Functional medicine practitioners, therefore, have a way to address fibroids and endometriosis while simultaneously improving their patients' overall health. Such is the wonder and beauty of functional medicine.

Neurotransmitters: A Functional Medicine Approach to Neuropsychiatry

Jay Lombard, MD

Introduction

Neurotransmitters are the chemical messages of the central nervous system. There are over 50 substances recognized as molecules that function as neurotransmitters, including peptides, nitric oxide, neurotrophic factors, and cytokines. However, we will limit the current discussion to the “classic” neurotransmitters involved in neuropsychiatry. These include the catecholamines, dopamine and serotonin; the amino acid neurotransmitters, gamma-aminobutyric acid (GABA) and glutamate; and the amine neurotransmitter, acetylcholine.

A brief overview will be provided regarding the metabolic processes involved in the synthesis and release of these neurotransmitters, their neuroanatomical locations, and the relationships of neurotransmitter imbalances to specific neuropsychiatric disorders. We will also discuss developments in the assessment of neurochemical imbalances, including indirect measures of brain activity through peripheral biomarkers and through the use of neuroimaging procedures. Unfortunately, with few exceptions, measurements of blood and urine metabolites are often an inaccurate reflection of neuronal activity. More often than not, serum and urine measurements of neurotransmitter metabolites reflect peripheral rather than central activity and should not be used to make clinical decisions concerning neurochemical imbalances in individual patients. Conversely, recent advances in PET scanning and various MRI modalities can provide useful information regarding specific structural and functional brain properties involved in the pathogenesis of neuropsychiatric disorders.

Finally, we will discuss ways in which the clinician can integrate an understanding of the relationships of specific neurotransmitter imbalances with functional brain disorders, and then modulate some of these imbalances utilizing a functional medicine approach.

Overview of the Classic Neurotransmitters

The Catecholamines

Dopamine. Dopamine is an important endogenous catecholamine that binds to specific membrane recep-

tors and plays a key role in the control of locomotion, learning, working memory, cognition, and emotion.⁶²⁹ Dopamine is synthesized in the substantia nigra and projects to cortical and subcortical limbic regions via mesocortical and mesolimbic pathways. It is synthesized by enzymatic modification of the amino acid tyrosine in a series of steps; the rate-limiting enzyme in this process is tyrosine hydroxylase. Brain tyrosine levels are usually adequate to saturate tyrosine hydroxylase and therefore precursor strategies involving exogenous tyrosine administration are not useful in enhancing dopamine synthesis or raising brain dopamine levels.⁶³⁰

There are two types of dopamine receptors, the D1 family of receptors, which are G protein coupled and stimulate adenylyl cyclase, and the D2 family, which are also coupled to G proteins but inhibit adenylyl cyclase.

From a neurobehavioral perspective, dopamine plays a critical role in motivation, reward-seeking behavior and attentional processes.^{631,632} The high density of dopaminergic projections in limbic regions suggests that dopamine is also involved in orientation toward “affect-laden experience” and response to stress. Imbalances of dopamine in limbic regions have been linked to ADHD (prefrontal circuits),^{633,634,635} schizophrenia (mesolimbic cortex),⁶³⁶ and subcortical neuropsychiatric disorders including Tourette’s syndrome^{637,638} and possibly autism.⁶³⁹

Indirect measures of CNS dopamine activity, including measurements of CSF HVA (homovanillic acid) levels (the end product of dopamine metabolism), have been associated with positive symptoms of schizophrenia such as hallucinations and paranoia. More recently, SPECT and PET scan studies have provided a window into specific abnormalities of dopamine dysfunction in discrete brain regions.⁶⁴⁰

Nuclear brain scans can examine either perfusion or receptor occupancy and density. Perfusion studies are based on the premise that blood flow is coupled to metabolic activity and thereby inferences can be made regarding hyperfunctional or hypofunctional brain areas. Receptor studies can provide estimates of either increased or decreased receptor density in specific neuropsychiatric conditions. Examples of perfusion abnormalities include findings of reduced frontal lobe glucose utilization in adult ADHD patients.⁶⁴¹ In schizophrenia, receptor density measures have revealed increased D2 receptor density, supporting the notion that psychosis

is related to hyperdopaminergic activity in the mesolimbic cortex.⁶⁴²

Dopamine and its receptors can be adversely affected by genetic and environmental factors. A prime example of an environmental toxin that affects dopamine is MPTP. MPTP can produce a hypodopaminergic state indistinguishable from Parkinson’s disease.⁶⁴³

Serotonin. It is widely accepted that serotonin is critically important in neurobehavioral processes including mood and anxiety.⁶⁴⁴ Serotonin is synthesized from the amino acid tryptophan via the rate-limiting step tryptophan hydroxylase. Unlike tyrosine hydroxylase (the rate-limiting step in dopamine synthesis), tryptophan hydroxylase is not saturated, and thus dietary sources of tryptophan can have a significant effect on serotonin synthesis.⁶⁴⁵

Serotonergic cells are present in the brain stem and have extensive projections to limbic regions and the cortex. There are many serotonin receptor subtypes: the 5HT_{1A} and 5HT₃ which predominate in limbic structures and the 5HT₂ subtype located primarily in the neocortex. 5HT₁ and 5HT₂ receptors are G protein coupled where they influence cAMP levels. The 5HT₃ receptors are ion gated and are primarily inhibitory in function.

Serotonergic imbalances are related to mood disorders, anxiety syndromes including OCD,^{646,647} PTSD and panic disorder, and autism.⁶⁴⁸ An indirect assessment of serotonin activity can be measured through platelet serotonin binding sites. 5HT₂ receptors are localized on platelets in the periphery, and decreased platelet serotonin binding has been observed in patients with major depression.⁶⁴⁹

Neuroimaging modalities, including PET and functional MRI, have revealed abnormalities in discrete anatomical regions involved in mood and anxiety disorders. For instance, in patients with major depressive disorder, reduced activity in the anterior cingulate and medial orbital frontal cortex region has been reported.⁶⁵⁰ These limbic regions are densely innervated by serotonergic neurons. PET scan studies utilizing a serotonin tracer molecule demonstrated significant abnormalities in serotonin synthesis in autistic children compared to controls.⁶⁵¹

Like dopamine, serotonin levels are influenced by genetic and environmental factors. Functional polymorphisms of 5HT transporter genes have been associated with depression,⁶⁵² autism,⁶⁵³ and (conversely) with centenarians.⁶⁵⁴ Environmental factors such as

prolonged persistent stress activate the hypothalamic-pituitary-adrenal axis (HPA) and cause hypersecretion of ACTH and cortisol (see earlier discussion in this chapter of the HPA axis). These changes may alter chaperone proteins, which are essential for maintaining serotonin receptor structural integrity, and thus lead to a hyperserotonergic state.

Amino Acid Neurotransmitters: GABA and Glutamate

GABA is regarded as the principal inhibiting neurotransmitter in the brain. GABA is formed via a metabolic pathway called the GABA shunt. The initial step in this pathway utilizes alpha ketoglutarate, which is then transaminated to form glutamate, the immediate precursor of GABA. Glutamate is then decarboxylated by glutamic acid decarboxylase (GAD) to form GABA. Pyridoxine is the key cofactor in GAD activity, positively favoring the conversion of glutamate to GABA. Pyridoxine-deficient states are associated with low CSF GABA levels and improve with B6 administration.⁶⁵⁵

GABA and glutamate are ubiquitous in the CNS and have a reciprocal, yin-yang interaction of inhibition and excitation. As mentioned earlier, GABA is the principal inhibiting neurotransmitter, whereas glutamate acts as the principal excitatory neurotransmitter in the brain. Glutamate produces neuronal depolarization via binding to either NMDA, AMPA [2-amino-3-(3-hydroxy-5-methyl-4-isoxazolyl) propionic acid], or kainite receptor sites. One of the most important physiological roles of glutamate is in learning processes⁶⁵⁶ such as synaptic remodeling and long-term potentiation (LTP), a process in which long-term memories are acquired and stored.

Glutamate is also involved in neuronal injury and apoptosis. Excessive glutamate produces a cascade of destructive molecular events, including elevated cytoplasmic and mitochondrial membrane calcium, uncoupling of the mitochondrial membrane potential, and elaboration of caspases and phospholipases. (See Chapter 30 for more on energy production and oxidative stress.) Excess glutamate has been linked to several neurodegenerative disorders including Alzheimer's disease,⁶⁵⁷ ALS,⁶⁵⁸ and multiple sclerosis, and neuropsychiatric disorders including epilepsy, bipolar disease,⁶⁵⁹ migraine,⁶⁶⁰ and schizophrenia.⁶⁶¹

Measurements of GABA and glutamate in the CNS are exceedingly difficult, but inferences can be made by measurements of N-Acetyl aspartate (NAA) through

magnetic resonance spectroscopy.^{662,663} Decreased levels of NAA measured by MRS have been reported in the hippocampus of Alzheimer's and bipolar disorder patients, an indication of hyperglutaminergic dysfunction in these conditions.

Acetylcholine (ACH)

The neurophysiological activity of acetylcholine in the hippocampus supports its primary role in the CNS in cognitive processes. ACH is synthesized from choline and acetyl-coA via the enzyme choline acetyltransferase. Pharmacological manipulation of acetylcholinesterase, the enzyme which degrades acetylcholine, is currently employed to treat Alzheimer's disease, which is regarded as a cholinergic deficit disorder.⁶⁶⁴

Functional Brain Approaches in Practice

Table 32.5 provides an overview of specific strategies employed to modulate neurotransmitter imbalances in neuropsychiatric conditions.

Table 32.5 Strategies to Modulate Neurotransmitter Imbalances in Neuropsychiatric Conditions

Neuro-transmitter	Potential Indications	Compound
Dopamine	ADHD	Folic acid Essential fatty acids (EFAs) Vitamin A
Dopamine blockade	Schizophrenia Autism	Melatonin
GABA	Anxiety Seizures	Pyridoxine
Excess glutamate	Epilepsy Migraine Bipolar disease Neurodegenerative disease	Magnesium EFAs Melatonin
Serotonin	Depression	Folic acid EFAs 5HTP, LAC
Acetylcholine	Dementia Mild cognitive impairment	Huperzine Acetylcarnitine

Dopamine and Serotonin Imbalances: Implications for the Treatment of ADHD and Depression

Augmentation strategies used to increase dopamine for the treatment of ADHD are based on observations that dopamine levels are preferentially reduced in frontal brain regions of adult ADHD patients.⁶⁶⁵ Furthermore, genetic abnormalities related to dopamine transporter proteins have been reported in ADHD patients,⁶⁶⁶ supporting the concept that symptoms of ADHD may result from a relative hypodopaminergic state.

Several nutraceutical approaches have been proposed to augment the hypodopaminergic state of ADHD patients, including specific herbal supplements, amino acids, and minerals. Our discussion will focus primarily on folic acid and omega-3 fatty acids. It should be noted that neither folate nor essential fatty acids enhance dopamine levels directly. These nutraceuticals may exert their influence on postsynaptic dopamine receptor sites by enhancing the threshold of neuronal signaling.

Neurotransmitter interactions with postsynaptic receptors induce conformational changes in the receptor. Through this engagement, referred to as signal transduction, changes in the phosphorylation status of ion channels, second messenger systems such as cyclic AMP (cAMP) and gene transcription factors alter the behavior of targeted neuronal cells. An elaborate example of signal transduction is the binding of dopamine to D1 receptors. The binding of dopamine stimulates the activity of adenylyl cyclase, which in turn catalyzes the conversion of ATP into cAMP. cAMP then transfers a phosphate group to specific intracellular proteins, a process that subsequently modifies their activity.

Postsynaptic cAMP production, which occurs through agonist stimulation of the postsynaptic receptor, initiates what may be regarded as a “pro-life” signaling cascade. One of the effects of cAMP is activation of protein kinase A, an enzyme that phosphorylates many substrates including cAMP response element binding protein (CREB). Phosphorylation of CREB increases the expression of the anti-apoptotic factor BCL-2. BCL-2 inhibits apoptosis by stabilizing the mitochondrial membrane potential, inhibiting the opening of the mitochondrial permeability transition pore and preventing the release of “death-driving” cysteine proteases involved in programmed cell death.

One of the most important physiological effects of cAMP in the brain involves its regulation of heat shock proteins. Brain cells respond to adverse changes in the cellular milieu, including free radicals, insulin receptor subsensitivity, elevated temperature, and ionic imbalances, through the production of heat shock proteins. Heat shock proteins assist in the holding of newly synthesized proteins, the degradation of malformed protein, and maintenance of calcium homeostasis within the endoplasmic reticulum.⁶⁶⁷ Neurochemical processes that augment cAMP promote the expression of heat shock proteins and enhance neuronal cell survival, whereas molecular factors that diminish cAMP reduce heat shock proteins and lead to increased risk of apoptosis.⁶⁶⁸

Protein phosphorylation can be regarded as a “final common pathway” involved in neurotransmitter signal transduction and may link emotional states with physical changes in the body. The relationship of catecholamine agonists with cell survival at a molecular level may help to explain the observed benefits of antidepressant therapy and decreased mortality in patients with cardiovascular disease, and perhaps why happy people seem to live longer than sad people.

In addition to receptor modification and protein conformational changes that occur through phosphorylation, methylation of phospholipids may alter activity of dopamine receptors. Richard Deth, at Northeastern University, first demonstrated that inhibiting methylation at D4 receptor sites resulted in reduced G protein activation and reduced intrinsic activity of the receptor. Conversely, increased methylation of the D4 receptor, which is enhanced by folic acid in the form of methyltetrahydrofolate, increases intrinsic dopamine activity.⁶⁶⁹

Clinically, folate-deficient states are associated with symptoms of depression, apathy, and impaired concentration,⁶⁷⁰ and they have been linked to a poor response to antidepressants as well.⁶⁷¹ These symptoms, while nonspecific, may result from either a hypodopaminergic or hyposerotonergic state. Folate deficiency may produce a catecholamine deficit, either through impaired methylation of postsynaptic receptors, or through folate-dependent enzymatic pathways. Folic acid is a cofactor in production of tyrosine hydroxylase, the rate-limiting factor in dopamine synthesis, and also in tryptophan hydroxylase, the rate-limiting step in serotonin synthesis. Several studies have demonstrated an inverse relationship between low folate levels and mood, as well as response rate and relapse rate to antidepressants.⁶⁷² In

support of these observations, reduced blood folate levels have been correlated with reduced levels of CSF serotonin (SHIAA).⁶⁷³

Tryptophan and Brain Serotonin

L-tryptophan is the immediate precursor to brain serotonin, a fact which has led many clinicians to employ this amino acid to treat hyposerotonergic states, including depression, insomnia, and anxiety. The importance of tryptophan in the regulation of mood is supported by the observations that dietary depletion of tryptophan leads to increased release of hypothalamic corticotropin-releasing factor (CRF), increased plasma cortisol, and an exacerbation of depression symptoms.⁶⁷⁴ Hypercortisolemia is a frequent finding in depressed patients and may be a consequence of a loss of normal inhibitory function of tryptophan on CRF activity.

It should be noted that dietary administration of L-tryptophan is generally an inefficient way to enhance brain serotonin production due to competitive inhibition with other large neutral amino acids to cross the blood-brain barrier. An innovative strategy to bypass this limitation involves the utilization of alpha lactalbumin (LAC). Ingestion of LAC enhances serotonin synthesis in animals and humans, lowers cortisol levels, and induces anxiolytic effects.⁶⁷⁵

Omega-3 Fatty Acids

Role in dopamine, serotonin, and glutamate imbalances. The omega-3 fatty acids, which are constituted in the phospholipids of all cell membranes, exert direct and indirect influences on neurotransmission through modifications at the postsynaptic receptor. They influence signal transduction by inhibiting the hydrolysis of inositol triphosphate (IP3), an effect that closely resembles the activity of lithium. Essential fatty acids also inhibit membrane phospholipase activity,⁶⁷⁶ and reduce arachidonic acid release from neuronal cell membranes.⁶⁷⁷ Because arachidonic acid has been demonstrated to increase glutamate release, block reuptake of glutamate, and potentiate NMDA receptors,⁶⁷⁸ essential fatty acids may be regarded as indirect glutamate antagonists and should be considered as potential agents in excess glutamate states (bipolar disease, for example).

Omega-3 fatty-acid deficiency has been linked to diminished dopamine receptors in rats,⁶⁷⁹ and several researchers have found a direct correlation between

low plasma or membrane-bound essential fatty acids and depression.⁶⁸⁰

Potential neuroprotective mechanisms of omega-3 fatty acids:

- Modulation of sodium and calcium channels with reduction of electrochemically excitable tissue
- Inhibition of phospholipase activity
- Reduced synthesis and release of membrane bound arachidonic acid
- Downregulation of excitotoxic glutamate-mediated neurotransmission

Vitamin A and Hypodopaminergic States

Vitamin A has an important and often overlooked function in brain development and in the adult brain. The distribution of retinoid receptor proteins in the amygdala, hippocampus, and other paralimbic brain regions suggests that retinoid signaling plays a vital role in cognitive and affective processes. Isomers of retinoic acid induce cyclic-AMP response elemental binding protein (CREB) and stimulate the expression of brain-derived neurotrophic factor (BDNF).⁶⁸¹

Brain retinoic acid acts to upregulate D1 receptors and dopamine-dependent cAMP.⁶⁸² In animals, vitamin A deficiency results in a loss of hippocampal synaptic plasticity, and deficits in spatial learning, memory, and long-term potentiation.⁶⁸³

Defects in retinoid signaling pathways have been implicated in schizophrenia.⁶⁸⁴ Vitamin A deficiency may lead to diminished D1 receptor gene transcription. This D1 receptor hypoactivity may produce the characteristic “negative symptoms” of schizophrenia such as apathy, blunted affect, and lack of insight. D1 receptor deficits may also have a disinhibiting effect on limbic D2 receptors, leading to the “positive symptoms” of schizophrenia such as hallucinations and delusions. Vitamin A and retinoid analogs are currently being explored as novel therapeutics in schizophrenia.

Hyperdopaminergic States

There are few nutraceutical agents that can reduce or inhibit the hyperdopaminergic state associated with psychotic disorders. However, melatonin may be an exception. Melatonin is an indoleamine found in the pineal gland, where it functions to facilitate adaptive changes in circadian rhythms.⁶⁸⁵ Melatonin has a nocturnal pattern of secretion, exerting an inhibiting influ-

ence on neurons and promoting sleep via stimulation of adenosine.

Melatonin and adenosine are potent inhibitors of dopamine and glutamate.⁶⁸⁶ Adenosine agonists have behavioral properties similar to dopamine antagonists. Melatonin and adenosine exert neuroprotective effects on mitochondrial function and have direct effects on the mitochondrial transition pore.⁶⁸⁷ This pore, referred to as the PTP channel, is opened in response to elevated cytosolic calcium and hypoxia; it induces pro-apoptotic molecular events. The ability of melatonin to inhibit PTP channel opening within mitochondrial membranes may account for its neuroprotective properties. An additional mechanism involved in the neuroprotective effects of adenosine involves homocysteine metabolism. Elevated homocysteine has well-known adverse effects in the CNS, including upregulation of excitotoxic NMDA receptors. Homocysteine administration in animals has been demonstrated to trap adenosine as s-adenosylhomocysteine and increase cortical hyperexcitability. Thus, depressed adenosine that occurs as a consequence of elevated homocysteine may be a critical mechanism in neurodegenerative disease and stroke.⁶⁸⁸

Like melatonin, adenosine exhibits neuroprotective activity by signaling neurons to reduce metabolic activity and preserve mitochondrial ATP stores. Elevated adenosine, which occurs in response to ischemia and hypoxic conditions, may act to “shut cells off” and depress metabolic activity in the mitochondria as a compensatory mechanism during periods of high metabolic stress. In this conceptual model, melatonin and adenosine can be considered molecular signals associated with inhibitory processes—reduced metabolic activity, lower mitochondrial “burning of fuel,” and even sleep. Support for this notion is the observation that melatonin has a hypothermic effect.⁶⁸⁹ Melatonin deficiency has been reported in schizophrenia⁶⁹⁰ and autism,^{691,692} and administration of this hormone has been shown to improve sleep in patients with these disorders.^{693,694,695}

Magnesium: An Endogenous Glutamate Antagonist

Magnesium inhibits voltage-gated NMDA receptor channels and prevents excessive neuronal depolarization.⁶⁹⁶ Magnesium has been used successfully to treat eclampsia-related seizures,⁶⁹⁷ migraines,^{698,699} and in the setting of acute stroke as well.⁷⁰⁰

Acetylcholine Augmentation Approaches

There is considerable evidence that links cholinergic neurotransmission to cognitive processes and memory. In pathological states such as Alzheimer's disease, post-mortem studies consistently reveal reduced choline acetyltransferase activity and a reduced number of cholinergic neurons in the basal forebrain.⁷⁰¹

Current pharmacological approaches in the treatment of dementia inhibit the acetylcholine degrading enzyme, AChE, and hence raise synaptic acetylcholine levels by preventing degradation. Huperzine A, a traditional Chinese herbal medicine, acts as a potential AChE inhibitor with reportedly higher specificity at the active enzymatic site, longer duration of action, greater bioavailability, and fewer side effects than conventional AChE inhibitors currently approved for the treatment of Alzheimer's disease.^{702,703,704} Furthermore, Huperzine exhibits neuroprotective effects *in vitro* through non-competitive NMDA receptor antagonism,⁷⁰⁵ a biochemical effect that closely resembles memantine (Namenda), a drug approved for Alzheimer's patients to slow the progression of the disorder.

Carnitine, primarily in the form of acetylcarnitine, has been shown to raise brain acetylcholine levels, purportedly through stimulation of choline acetyltransferase.⁷⁰⁶ Acetylcarnitine also inhibits mitochondrial dysfunction through its antioxidant effects and, in a recent meta analysis of 21 double-blind studies of acetylcarnitine in the treatment of cognitive impairment and mild Alzheimer's disease, showed significant efficacy vs. placebo.⁷⁰⁷

Additional Level of Complexity

An additional level of complexity in human neurochemistry is involved when considering how neurotransmitters exert influence on other neurotransmitters. Some examples of these interactions in both normal and diseased states include the following:

- Prefrontal dopamine inhibits limbic dopamine, an example in nature of the adage, “think before you act.”
- In schizophrenia, low prefrontal dopamine “releases” limbic dopamine and leads to intense synaptic firing of emotional brain centers no longer under cortical influence.

- Serotonin can inhibit downstream effects of glutamate by enhancing calbindin, an intracellular calcium-binding agent.
- Several neurodegenerative diseases, including ALS, are associated with reduced calbindin activity in apoptotic targeted neurons.
- Nicotinic acetylcholine receptors stimulate dopamine release, enhancing attentional processes required for learning.
- A core neurobehavioral impairment in Alzheimer's disease involves reduced attention and apathy to surroundings.

Summary

Neurochemical processes exist in a dynamic equilibrium and neuropsychiatric disorders reflect an imbalance between excitatory and inhibiting influences. These imbalances are affected by genetic and environmental factors, and they produce dysfunctional states through alterations in the phosphorylation states of phospholipids and mitochondrial membranes. Inhibitory mechanisms exerted at a molecular level by GABA, serotonin, melatonin, and adenosine promote hyperpolarization; at a macromolecular level, physiological effects associated with restoration are noted. Conversely, excitatory processes, mediated primarily through glutamate, exert a depolarizing effect on neurons, which can be considered the signal of activity and stimulation. Like other examples in nature, neither state is inherently harmful or associated with pathological processes. Neuropsychiatric disease results when there is an imbalance in the dynamic homeostasis between these excitatory and inhibiting forces.

Thyroid

Lara Pizzorno, MA Div, MA Lit, LMT, and William Ferril, MD

Earlier in this chapter, a detailed discussion on the many causes and manifestations of thyroid dysfunction was provided. Here, we will focus on applying that information to the challenge of improving thyroid function in patients. Depending on the clinician's assessment of where the most significant problems lie for each patient, the eight areas of the functional medi-

cine matrix can indicate many useful approaches for supporting and improving thyroid function.

Interpreting Laboratory Findings

Typical ranges for normal serum thyroid hormone values are:

T ₄	4.8–13.2 µg/dl
Free T ₄	0.9–2 ng/dl
T ₃	80–200 ng/dl
TSH	0.4 to 4.0 mIU/L for those with no symptoms of an under- or overactive thyroid.

If the patient is being treated for a thyroid disorder, the TSH should be between 0.3 and 3.0 mIU/L. Some people with a TSH value over 2.5 mIU/L who have no signs (that is, no other abnormal thyroid function tests) or symptoms suggestive of an underactive thyroid may develop hypothyroidism sometime in the future. Anyone with a TSH above 2.5 mIU/L, therefore, should be followed very closely by a doctor. Normal value ranges may vary slightly among different laboratories.⁷⁰⁸ The sensitive thyrotropin assay is considered the most useful method of detecting thyroid dysfunction.^{709,710,711}

When interpreting thyroid blood tests, it's important to note that results may be misleading for a variety of reasons:

- A test result within laboratory reference limits is not necessarily normal for a specific individual. A study in 2002⁷¹² found that “each individual had a unique thyroid function” and “high individuality causes laboratory reference ranges to be insensitive to changes in test results that are significant for an individual.”
- Another study of the problems associated with inter-laboratory differences used TSH and TSH with free thyroxine as examples of tests where such differences can “markedly affect the clinical interpretation of tests.”⁷¹³
- In chronic stress, high cortisol levels inhibit the pituitary's production of TSH while also causing displacement of thyroid protein off its carrier protein. Despite the fact that thyroid hormone becomes depleted, a blood test will show a normal TSH result. Patients under chronic stress should be

evaluated using their armpit temperature immediately before arising (see below) and a 24-hour urine test to assess thyroid hormone levels.

- Cortisol and thyroid have a complex relationship. In normal functioning, cortisol is needed in the liver and kidneys for the conversion of T_4 to T_3 . In conditions of cortisol excess (acute stress), the generalized pattern is characterized by a trend toward lowered TSH production and a blunted TSH response to TRH, a decline in T_3 , and an increase in rT_3 .⁷¹⁴ When acute stress becomes prolonged, chronic stress and adrenal exhaustion ensue, the body's ability to produce sufficient cortisol for the T_4 to T_3 conversion may become compromised, and even individuals whose thyroid gland is producing normal amounts of T_4 , as determined by laboratory test, may be functionally deficient in thyroid hormone. In brief, both excess and insufficient cortisol negatively impact the conversion of T_4 to T_3 , by slightly different mechanisms.
- Anxiety caused by the blood draw can temporarily increase free values of thyroid hormone. Anxiety activates the stress response, which activates lipoprotein lipase, resulting in an elevation in free fatty acid levels. Free fatty acids displace thyroid hormone from its carrier, temporarily raising free thyroid hormone levels.
- Certain medications can also inappropriately elevate levels of thyroid hormones by causing their displacement off thyroid binding globulin. These include aspirin (and other nonsteroidal anti-inflammatories),⁷¹⁵ phenytoin,⁷¹⁶ diazepam,⁷¹⁷ and increased blood heparin.⁷¹⁸

Measuring Basal Body Temperature

Basal body temperature, which is controlled by the thyroid and can be a better indicator of how much T_3 is active inside cells than blood tests that measure T_4 , is a good way of assessing basal metabolic rate. Procedure:

- Shake down a thermometer to below 95 degrees and place it by the bed before going to sleep.
- Upon waking, place the thermometer under the armpit for a full 10 minutes.
- Remain as still as possible, resting with the eyes closed.
- Record the temperature for at least three consecutive mornings, preferably at the same time of day. Menstruating women must check basal body temperature on the second, third, and fourth days of menstruation. Men and postmenopausal women can check on any three consecutive days.

Low thyroid function can have a variety of underlying causes. It's important to pin down the source of the problem and match the therapeutic approach to the patient's specific needs. Consider the following general types of dysfunction, indicated by the relationships among various laboratory findings:

1. Pituitary dysfunction is suggested by blood levels low in both T_4 and TSH.
2. If blood levels of TSH are elevated, yet T_4 levels are still low, this indicates that the pituitary has responded properly, but the thyroid gland is not responding to TSH by synthesizing T_4 .
3. If TSH is elevated despite normal blood levels of T_4 , this suggests an autoimmune problem resulting in subclinical hypothyroidism.
4. The presence of low basal body temperature and a high reverse- T_3 -to- T_3 ratio is suggestive of Wilson's disease.
5. If both TSH and T_4 levels are normal, but clinical signs indicate low thyroid activity, this suggests inadequate conversion of T_4 to T_3 in peripheral tissues, which may be due to iodothyronine iodine dysfunction.
6. If T_3 levels are adequate, but thyroid function is still low, this suggests an inability of T_3 to attach to receptors inside the cells and activate enzymes, due either to a malformation in T_3 (a high ratio of reverse- T_3 -to- T_3 may be evidence of this situation) or the intracellular receptor sites.

Many factors can contribute to these problems. Using the information presented earlier in the chapter, we will take a "tour" of the functional medicine matrix to identify specific approaches the clinician can use to help patients improve thyroid function.

The Matrix: Environmental Inputs

Diet And Nutrients

The influence of diet upon health can scarcely be overstated (see Chapter 26), and there are many foods and nutrients that can hinder or support thyroid function.

Goitrogens may block iodine utilization. Both the isoflavones found in soybeans^{719,720} and the isothiocyanates found in Brassica family vegetables⁷²¹ are goitrogens, which appear to reduce thyroid hormone output by blocking the activity of thyroid peroxidase, the

enzyme responsible for adding iodine to the thyroid hormones. While soy foods and Brassica family vegetables (turnips, cabbage, broccoli, cauliflower, Brussels sprouts, mustard greens, kale, kohlrabi, rutabaga) are the primary sources of goitrogens, they are also found in small amounts in peanuts, pine nuts, millet, peaches, strawberries, spinach, and cassava root. Both isoflavones and isothiocyanates appear to be heat-sensitive, and limited research suggests cooking, specifically boiling, lowers the availability of these substances.^{722,723} However, since boiling crucifers results in the loss not only of goitrogens but of important nutrients as well, patients for whom goitrogens may be problematic can be advised to briefly steam these vegetables and consume them in modest amounts.

Excess iodine. Although iodine is necessary for proper thyroid function, excessive intake of iodine can suppress TSH levels and inhibit thyroid hormone synthesis in susceptible individuals.⁷²⁴ Although the RDA for iodine in adults is only 150 mcg, the average intake of iodine in the U.S. is estimated to be over 600 mcg per day (probably due to the ubiquitous use of iodized salt). Excess iodine (high urinary iodine concentration) and low TSH can be predictable factors for a recovery from hypothyroidism due to Hashimoto's thyroiditis after restricting iodine intake.⁷²⁵ A case of neonatal iodine overload (from iodinated skin disinfectants) causing transient hypothyroidism was reported in 2005,⁷²⁶ so care should be taken in the use of such products for infants.

Foods rich in nutrients needed for T_4 manufacture include:

- **Iodine:** sea vegetables (kelp, dulse, hijiki, nori, arame, wakame, kombu), clams, shrimp, haddock, oysters, salmon, sardines, eggs
- **Zinc:** fresh oysters, ginger root, lamb chops, pecans, split peas, Brazil nuts, whole wheat, rye, oats, almonds, walnuts, sardines
- **Vitamin E:** wheat germ oil, sunflower seeds, almonds, peanut oil, olive oil, wheat germ, peanuts
- **Vitamin A:** liver, red chili peppers, greens (collard, turnip, kale, Swiss chard, beet greens), apricots, winter squash, cantaloupe, papaya, nectarines, peaches, cod liver oil ("Free retinol is not generally found in foods. Retinyl palmitate, a precursor and storage form of retinol, is found in foods from animals. Plants contain carotenoids, some of which are precursors for vitamin A (e.g., alpha-carotene and beta-

carotene). Yellow and orange vegetables contain significant quantities of carotenoids. Green vegetables also contain carotenoids, though the pigment is masked by the green pigment of chlorophyll."⁷²⁷)

- **Vitamin B2 (riboflavin):** Brewer's yeast, organ meats, almonds, wheat germ, wild rice, mushrooms, egg yolks
- **Vitamin B3 (niacin):** Brewer's yeast, rice bran, wheat bran, peanuts with skin, liver, light meat of turkey and chicken
- **Vitamin B6 (pyridoxine):** Brewer's yeast, sunflower seeds, wheat germ, tuna, liver, soybeans, walnuts, salmon, trout, lentils, lima beans, navy beans, garbanzos, pinto beans, brown rice, bananas
- **Vitamin C:** Red chili peppers, guavas, red sweet peppers, parsley, greens (collard, turnip, mustard, kale), strawberries, papaya, citrus fruits (oranges, lemons, grapefruit)

Foods rich in nutrients needed for $T_4 \rightarrow T_3$ conversion include:

- **Zinc:** fresh oysters, ginger root, lamb chops, pecans, split peas, Brazil nuts, whole wheat, rye, oats, almonds, walnuts, sardines
- **Selenium:** Brazil nuts. One Brazil nut provides approximately 139 mcg; 200 mcg/day is the recommended dosage. Excess selenium can interfere with enzyme systems related to sulfur metabolism and can be toxic in amounts greater than 900 mcg/day.⁷²⁸

Foods rich in nutrients needed for T_3 binding to intracellular receptors are those rich in Vitamin A: liver, red chili peppers, greens (collard, turnip, kale, Swiss chard, beet greens), apricots, winter squash, cantaloupe, papaya, nectarines, peaches, cod liver oil

Nutritional Supplementation Considerations for Improving Thyroid Function:

- Zinc, vitamin E, vitamin A, B2, B3, and B6 are all involved in the manufacture of thyroid hormone.
- Zinc is a cofactor in one form of the deiodinase enzyme that converts T_4 to T_3 , and zinc deficiencies can prevent the proper activation of DNA programs (zinc finger malfunction).
- Low zinc levels are common in the elderly (and even more severe in the institutionalized elderly),⁷²⁹ and the risk of hypothyroidism increases with age.^{730,731}
- Vitamin A is also necessary for the formation of intracellular receptors for T_3 .⁷³²

- Selenium, a cofactor in another of the deiodinase enzymes, is estimated to be markedly deficient in diets worldwide.^{733,734} Selenium has been demonstrated to decrease thyroid antibody levels in autoimmune thyroid conditions^{735,736} such as Hashimoto's, which is thought to constitute a significant percentage of subclinical hypothyroidism.⁷³⁷
- Antioxidant supplementation may be particularly important if environmental toxins are a potential contributing factor.^{738,739,740,741} Supplementation with vitamins C, E, and *Curcuma longa* (turmeric), for example, has been shown to increase thyroid function in rats with methimazole-induced hypothyroidism.⁷⁴²

Exercise

Exercise stimulates thyroid gland secretion, increases tissue sensitivity to thyroid hormone, and is well known for its stress-relieving effects. Dieting has consistently been shown to cause a decrease in metabolic rate as the body strives to conserve fuel.⁷⁴³ Exercise, unfortunately, has not consistently been shown to prevent this decline in metabolic rate in response to dieting.^{744,745,746} However, the many other benefits of exercise, including both weight training (which builds muscle mass) and aerobic exercise (which improves the body's use of oxygen), have been described elsewhere (see Chapters 13 and 29), and constitute reason enough for including it in the overall program.

Xenobiotics

Exposure to toxic levels of heavy metals can interfere with thyroid function.⁷⁴⁷ The destructive effects of heavy metals (lead, cadmium, mercury) are well documented and are discussed elsewhere in this book (see Chapters 13, 22, and 31). Lead and mercury invade the thyroid gland and disrupt the production of thyroid hormones, or induce minute alterations in their molecular structure, so they are no longer recognized by cellular receptors. Heavy metals can also impair liver and kidney function, decreasing conversion of T_4 to T_3 .

In agricultural areas, the likelihood of pesticide contamination in the water is higher. Tap water may be contaminated with minute amounts of insecticides, weed killers, and artificial fertilizer. Pesticides have been shown to interfere with thyroid function and to

increase cancer risk. People not only drink and cook with water, but also bathe and shower in it, thus absorbing chemicals through the digestive tract, skin, and respiration (from the vapors).

Hormone and antibiotic residues in meat and dairy products, food-borne bacteria, chemicals in cleaning products, food additives, cosmetics, and the metabolic by-products of unfriendly gut bacteria can denature thyroid hormones, producing reverse T_3 , and can also impair the activity of the liver and kidneys, thus decreasing conversion of T_4 to T_3 .

A significant correlation exists between smoking and Graves' disease.⁷⁴⁸ Fluoride is a direct antagonist to, and therefore inhibits utilization of, iodine.⁷⁴⁹

Medications

A number of prescription drugs can affect thyroid hormone production and delivery:

- Lithium has multiple effects on thyroid hormone synthesis and secretion.^{750,751}
- Certain antipsychotics can compromise thyroid function.⁷⁵²
- Amiodarone (Cordarone), which is used to treat arrhythmia, contains iodine and can induce hypothyroidism.^{753,754}
- Somatostatin and dopamine inhibit TSH secretion.⁷⁵⁵
- Liver enzyme activity (and thus the rate of clearance of thyroid hormone) is elevated by phenytoin for seizure disorders, the antibiotic rifampin for tuberculosis, and the psychiatric medicine carbamazepine.

Trauma

- **Surgery:** Overt hypothyroidism may be caused by thyroid surgery and ablation to correct hyperthyroidism.
- **Radiation:** Ionizing radiation from medical and dental x-rays, particularly those received in childhood, can adversely affect thyroid function, as can radiation therapy for various cancers. A 2004 review indicated that "radiotherapy-induced thyroid abnormalities remain underestimated and underreported."⁷⁵⁶

The Matrix: Hormonal and Neurotransmitter Imbalances

Only a select few hormones directly activate or repress the genetic programs contained within the cell nucleus: steroids, vitamin A, and thyroid hormones. The relative proportion of each will determine which proteins are present or absent, and whether sufficient body protein is produced for maintenance and repair.⁷⁵⁷ Protein provides the building blocks for the metabolically active constituents of body tissue. Examples of metabolically active protein-containing molecules dependent upon thyroid hormone activation of genes include actin, myosin, sodium/potassium ATPase, enzymes, and certain hormone receptors. Thus, low thyroid function leads to deficient regeneration information in key enzymes that perpetuate metabolism.

The formation of catecholamine receptors is dependent upon reception of thyroid hormone messages, so low thyroid function can both contribute to and mimic adrenal exhaustion. Since the thyroid message directs the activation of genes that increase the synthesis of key hormones and hormone receptors as well as metabolic enzymes, thyroid hormone deficiency sets off a chain reaction of other hormone deficiencies, accelerating the aging rate. For example, the amount of thyroid message received determines the rate of growth hormone synthesis within the pituitary.

The Matrix: Oxidation-Reduction Imbalances and Mitochondropathy

Thyroid hormones direct cellular DNA to increase the manufacture rate of cellular mineral pumps and mitochondrial combustion chamber components. ATPase is one of the enzymes dependent upon thyroid hormone activation of genes for its production. The sodium/potassium ATPase pump is responsible for trapping the energy the cell uses to charge its membrane. Body cells utilize the electrical charge within their membrane to protect themselves and to perform the cellular work of living. The more pumps, the more charge generated, and the more calories burned to maintain it. Fewer pumps lead to fewer calories burned. Fewer calories burned leads to a lower metabolic rate.^{758,759}

For this reason, EKG voltage tends to be diminished, and armpit temperature before getting out of bed is less than 97.6 degrees in patients with peripheral thyroid resistance, despite normal free serum levels of T_4 , T_3 and reverse T_3 .⁷⁶⁰

No matter what the raw fuel consumed (protein, fat, or carbohydrate), the mitochondria can only burn acetate. Many thyroid problems are made worse by specific vitamin deficiencies that impede the processing of raw fuels into acetate. For this reason, common signs of thyroid deficiency, like cold intolerance and weight gain, worsen with nutritional deficiencies (see above under Environmental Inputs/Diet and Nutrients).

The higher the metabolic rate, the greater the oxidative stress. In patients with hyperthyroidism, supplementation with antioxidants such as lipoic acid and N-acetylcysteine should be considered. Interestingly, there is animal research emerging that indicates the presence of oxidative stress in hypothyroidism as well, although the data are still limited and controversial. One such study demonstrated protective effects of taurine against the oxidative stress of hypothyroidism,⁷⁶¹ while the other showed a similar action of vitamin E.⁷⁶²

The Matrix: Detoxification and Biotransformational Imbalances

Compounds that induce phase I activity, whether xenobiotic, drug or food, may contribute to a faster rate of clearance of thyroid hormone, increasing the need for the thyroid gland to produce more hormone to maintain normal levels. Studies suggesting that dioxin and polybrominated diphenyl ethers (PBDEs—flame retardants that are ubiquitous environmental contaminants) disrupt thyroid function have been conducted for many years on animals.^{763,764,765,766,767,768} Although there are problems in assuming a direct transference of such information to humans, the consistent findings in animal research draw our attention to significant concerns with these chemicals, such as increasing thyroid hormone clearance and decreasing serum T_4 and T_3 levels.⁷⁶⁹

Impaired detoxification may result in recycling of estrogen, a concern particularly during pregnancy, and in perimenopause when estrogen levels may fluctuate to abnormally high levels. Higher estrogen levels increase thyroid binding globulin, making it harder for cells to access thyroid hormone.

The Matrix: Immune and Inflammatory Imbalances

Subclinical hypothyroidism may cause a slight increase in homocysteine, although the research has not been entirely consistent (the link is much better documented for overt hypothyroidism).^{770,771} Other CVD risk factors, such as CRP and cholesterol, are well known to be higher in both subclinical and overt hypothyroidism.^{772,773,774} Preventive measures that address the inflammatory and lipid markers should be undertaken if needed (see Chapter 27).

Adrenal function forms a determinant for the presence or absence of thyroid antibodies; thyroid autoantibodies are highly correlated with secondary adrenal insufficiency.⁷⁷⁵

In one study, patients with dermatitis herpetiformis were found to have significantly increased abnormalities of thyroid function tests (32% vs. 4%), with significant hypothyroidism being the most common abnormality affecting 12 of the 56 patients.⁷⁷⁶ This is a good place to emphasize the connection between thyroid disorders and gluten intolerance, as the link has been demonstrated not only in dermatitis herpetiformis,⁷⁷⁷ but also in many autoimmune diseases, including Hashimoto's thyroiditis.⁷⁷⁸

Thyroid hormone directly activates cellular DNA programs, including some responsible for the manufacture of receptors for other hormones. Without their receptors, it does little good for these hormones to arrive, as they cannot deliver their information. Diseases may arise because of receptor formation deficiency or receptor destruction. Asthma, for example, is sometimes caused by a defect in the receptors needed by epinephrine to keep the airways open.

The Matrix: Digestive, Absorptive, and Microbiological Imbalances

Digestive and absorptive functions also need to be considered. Thyroid hormone information affects GI motility; a slowing of the digestive and absorptive processes increases the opportunity for unfriendly bacteria to feed and proliferate. Dysbiotic bacteria produce beta-glucuronidase, which deconjugates estrogen, sending it back into the circulation. High levels of estrogen stimulate increased production of thyroid binding globulin, making it harder for cells to access thyroid hormone. In

addition, a strong correlation exists among autoimmune diseases, intestinal permeability, and food allergy. In one study of 100 celiac patients, two also had overt autoimmune thyroid disease. After six months on a gluten-free diet, serologic autoantibody markers were undetectable in these patients.⁷⁷⁹ In patients in whom digestive imbalances may be a contributing factor, the 4R program should be considered (see Chapter 28).

The Matrix: Structural Imbalances (Cellular Membrane)

Thyroid hormones deliver information to the cell's DNA to direct the creation of membrane pumps (sodium/potassium/ATPase pumps) that enable the cell to trap some of the energy produced in the mitochondria for useful work and charge its membrane. Thus, the formation and maintenance of a healthy cell membrane is dependent upon thyroid function.

Attention deficit-hyperactivity disorder has been linked with peripheral thyroid resistance,⁷⁸⁰ which blocks the ability of thyroid hormone to deliver its information at the DNA level due to defective cellular membrane receptors. Vitamin A is necessary throughout the body, including the brain, for the activation of thyroid-dependent DNA receptors.

The Matrix: Mind and Spirit

The psychoneuroimmunological connection to endocrine function is well recognized. Lack of belief in something greater than oneself, in a teleological universe, lack of support, community, love—these are the most fundamental causes of an inability to utilize stressors as spurs to the expression of a continually evolving positive vitality. Chronic stress, particularly if unmitigated by an inner spiritual harmony that assigns a positive meaning, disrupts normal thyroid function at virtually every level:

- Stress suppresses the hypothalamus' release of TRH, the pituitary's release of TSH, the thyroid gland's production of thyroid hormones.
- Chronic stress results in increased production of inflammatory cytokines that block conversion of T_4 to T_3 and—by binding to the thyroid peroxidase enzyme, thyroglobulin, and TSH receptors—can prevent the manufacture of T_4 , and may also bind to the adrenal glands, pancreas, and parietal cells.

- Chronic stress promotes an overactive immune system and thus an increased likelihood that anti-thyroidal antibodies will be produced.
- Chronically high cortisol levels increase thyroid binding globulin levels in the bloodstream.
- Chronic stress may result in a state of adrenal exhaustion in which supplies of cortisol are depleted. Recall that cortisol is necessary for the conversion of T_4 to T_3 .
- Chronic stress depletes magnesium reserves. Insufficient magnesium significantly lessens the body's ability to relax and get the deep sleep needed for repair and rejuvenation.

Sources of stress may be physical as well as emotional, including head or bodily injury, chronic allergies or infections, poor diet, or lack of sleep.

Summary

This completes our overview of potential influences on thyroid function from the perspective of mechanisms and the functional medicine matrix. From cellular messaging to the impact of diet, toxic exposures, medications, oxidative stress, GI dysfunction, and age, to the important role of stress and the life of the mind and spirit, the thyroid is vulnerable at myriad points on the matrix. The clinical benefit of a thorough understanding of underlying function and the imbalances that result from disturbed function is that those imbalances can often be redressed through the same mechanisms. In other words, diets can be changed, toxic exposures eliminated or reduced, oxidative stress improved with antioxidants, energy production increased, GI function and detoxification improved, cellular messaging supported, and stress management implemented. These are among the many potential interventions discussed throughout this book that can help practitioners improve outcomes for their patients with thyroid disease and dysfunction.

Chapter 33

Stress, Spirituality, Poverty, and Community— Effects on Health

Robert J. Hedaya, MD, FAPA

Introduction

Just as one uses different levels of magnification to thoroughly examine a sample under a microscope, so must the practitioner of functional medicine become adept at assessing the patient's health using a variety of lenses and perspectives. Applying this analogy, a high-magnification lens enables one to evaluate certain aspects of the functional medicine matrix (e.g., molecular and metabolic processes involved in the restoration of health, such as hormonal regulation or detoxification pathways), while a lower-magnification but broader lens enables one to evaluate intrapsychic processes (e.g., mental constructs such as attitudes and religious beliefs), and a perspective of even lower magnification assesses the broader contextual processes involved in the restoration of health (e.g., socioeconomic status, culture, and community). In this chapter, we will explore the health impact of some intrapsychic (stress, spirituality, religion) and contextual factors (community and poverty), and then discuss some practical approaches the clinician can use to weave these essential components of health care into the clinical interaction.

Various psychosocial factors are well known to affect health.¹ A brief introduction to the topic was presented in Chapter 13. Now we will explore a few of those issues in greater depth. There is a consensus² based on more than 60 years of psychophysiological research that psychological and social factors are crucial determinants in a chain of events leading from psychosocial interaction to neuroendocrine-immune changes. These changes, in turn, can induce progressive disruptions of normal adaptive physiology, eventually leading to functional

changes, which ultimately become involved in an interactive and reverberating feedback loop potentially affecting all levels of human function.

It is critical that the practitioner of functional medicine understand the nature of these psychosocial factors, so that he/she can treat the entire person with maximum efficacy. Clinical experience indicates that a failure to take the psychosocial aspects of the functional medicine matrix into account via adequate assessment and intervention can undermine treatment effectiveness.

Defining the Problem: What Does the Functional Medicine Practitioner Face?

Determining whether or not intervention is needed at any level of observation and identifying the types of interventions most likely to be beneficial are constant challenges for the clinician. Dysfunctional processes (discussed throughout this text) must be assessed, and promoters of and resources for change have to be selected and applied. Given the limited resources of many patients (time, money, support in the personal environment for behavioral changes, ability to self direct and maintain altered behavioral patterns), practitioners must be judicious in deciding which interventions are likely to be most effective and most likely to induce change. Unfortunately, at this time, there is a scarcity of good research (or clinical consensus) on how to decide where to “pull on the web”—that is, which intervention(s) is/are likely to produce the greatest overall benefit for the investment of time, money, and effort. It is generally true that the more points of intervention, the more likely one is to stimulate change, but maintenance of change remains a challenge. Research

Section VI

A Practical Clinical Approach

does indicate that involvement of the patient in decision making is beneficial to the outcome.³

In the following sections, we will review the concept of stress, and the impact of poverty, community, and spirituality on health, with the aim of guiding the clinician in the development of a practical and personalized approach to the integration of these considerations into clinical care.

Stress

The modern physician should know as much about emotions and thoughts as about disease symptoms and drugs. This approach would appear to hold more promise of cure than anything medicine has given us to date.

—Hans Selye⁴

Stress is the salt of life.

—Hans Selye⁵

What is Stress?

According to Selye,⁶ “stress is the non-specific response of the body to any demand, and a stressor is any agent that produces stress at any time.” Stressors may be loosely classified as direct physical systemic threats (e.g., starvation, heat, cold, pain, hemorrhage) or “processive” (e.g., psychosocial threats such as social defeat, separation from the maternal object, social isolation, helplessness). While direct systemic threats are not processed primarily by the cortical and limbic areas of the brain, psychosocial stressors involve higher brain functions as part of the primary processing of the sensory input.⁷

Clinically, it is important to expand the working concept of stress to include both the psychosocial factors we often think about (e.g., separation, job loss, cultural context) as well as the stress response to episodes of low blood sugar, chronic pain, or food restriction.

More recently, the concepts of stress and homeostasis have become supplanted by more specific terms and concepts. Allostasis (the ability to achieve stability through change)⁸ is thought to occur via acute and chronic changes in the stress response system (neuroendocrine axes—principally the hypothalamic-pituitary-adrenal or HPA axis—and the immune, autonomic, cardiovascular, and metabolic systems). The current conceptualization is that chronic dysregulation of the HPA axis, the autonomic nervous system, and the immune system contributes to chronic alterations in metabolism

and inflammation,⁹ which then interact with other influences (e.g., nutrition, genetics) to cascade into specific diseases such as the metabolic syndrome, hypertension, cardiovascular disease, and even depression and cancer.^{10,11}

Acute stress induces changes that are generally thought to be essential and adaptive, while chronic stress is thought to exact a higher physiological price, creating an allostatic load, defined as the long-term effect of the physiologic response to stress.¹² The acute stress response induces different biological changes in the stress response systems than those induced by chronic stress.¹³

Sensitivity to psychosocial stressors is, for many of us, an essential aspect of our biological make up, and some degree of stress is both desirable and necessary.¹⁴ We appear to be programmed to respond to certain essential psychosocial events in a comparatively predictable manner, although significant individual variations in this reactivity, based on genetics (such as glucocorticoid receptor polymorphisms), context, and prior experience modify the manifestations of the individual response.¹⁵

From infancy to early adulthood, much of this response to chronic stress is not subject to modification, except by changes in the context of the individual. Infants separated from their mothers for prolonged periods display disruptions in a variety of neuroendocrine-immune functions (e.g., establishment of the normal diurnal variation in cortisol output,¹⁶ amygdala hyperfunction,¹⁷ alterations of markers of immune function, as well as behavioral disturbances such as excessive fear and addictive disorders).¹⁸ Despite the broad range of disrupted neuroendocrine-immune functions, some orphans, once they are adopted, will demonstrate normalization of hypothalamic-pituitary-adrenal function.^{19,20}

As we approach adulthood, however, cognitive appraisal of events and sensory input becomes possible, and we can determine, to some degree, what emotional valence (i.e., “charge” or tone) we assign to a given situation. This assignment of meaning then determines our individual definition of what is stressful, and that definition will influence our biological response. Thus, beliefs and attitudes are one focal point for stress management,²¹ and studies have demonstrated beneficial effects of the cognitive-behavioral approach.^{22,23,24,25}

Aside from the direct systemic stressors (e.g., hemorrhage, hypoglycemia) and obvious psychosocial stressors

(e.g., trauma, separation, divorce) frequently addressed in the medical literature, other forms of stress exist. In all likelihood these have an impact on allostatic load to greater or lesser degrees in each individual. Hillman and Ventura²⁶ note some current cultural stressors:

Alar on your apples; asbestos around your heating pipes; lead paint on the schoolroom ceiling; mercury in your fish; preservatives in your hot dogs; cigarette smoke in the diner; rays from the microwave; sprays, mothballs, radon, feathers, disinfectants, perfumes, exhaust gases; the glue and synthetics in your couch; antibiotics and hormones in your beef.

Hillman continues: “The greatest moral choice we can make today, if we are truly concerned with the oppressed and stressed lives of our clients’ souls, is to sharpen their sense of beauty.” Furthermore, if beauty is an objectification of pleasure, as George Santayana posits,²⁷ then with each styrofoam cup, each asphalt slab, each blank wall, each teetering telephone pole, we are, each of us, robbed of a bit of pleasure.

Beyond the “aesthetic anesthesia” described by Hillman, and beyond the fast pace of change in western society, we are often subject to other societal pressures:

- Two-income families are on the rise. Given the weakened extended family structure in many modern societies, daycare is now part of the psychosocial soil in which we grow our next generation. Our society has yet to attend to studies that demonstrate the significant effect such rearing may have on the stress response system and behavior,^{28,29} as well as later psychopathology.³⁰
- The quality of social relatedness predicts general health and mortality, and one’s emotional adjustment to stress.³¹ Unfortunately, in our mobile society, where job and residence change are the norm, the reliability of social support (scientifically defined as consisting of social networks, social relationships, and social integration³²) as a buffer against stress has diminished.
- Additional stressors include, but are not limited to, crime, terrorism, lengthening commute times in major cities, traffic, and a bulimic diet of fear-focused media input.

Clinical Interventions—Stress

Assessment of psychosocial factors. Simply asking a patient “What are the main stresses in your life?” can be very useful. Together, the clinician and patient can

generate a list of these stressors, so that they can be tracked and addressed. Such a list might read:

- marital problems
- job
- finances
- death of a close relative
- medical illness

The next step is to flesh out the complexities of each item on the list, asking questions such as:

- How long has this been going on?
- How hopeful do you feel about resolving this problem?
- What kinds of thoughts and feelings do you have when you think about this particular issue?
- What are you doing to address this problem?
- Do you think you need more help or would you like more help addressing this problem?

The clinician can use these inquiries to develop an assessment of the patient’s life stresses, a sense of how the person adapts to different kinds of stress, and to build better rapport. (More on building rapport can be found in Chapter 36, which focuses on *The Healing Relationship*.) As clinicians, we can empathize with our patients’ predicaments, perspectives, and feelings, via recollection of similar events in our own lives. If this understanding is checked out with the patient for validity, and if it informs the clinician’s actions, the patient will feel understood and well-connected, and those feelings will pay dividends in terms of compliance.³³ While not proven, it seems intuitive that an empathic relationship between clinician and client would also aid in stress reduction and improved satisfaction for both parties.

Planning the intervention. Once the stressors have been identified and explored, the clinician and patient work together on developing an intervention plan. Asking “Which of these stresses do you think needs to be taken care of first?” will help identify the most urgent priority. Lifestyle measures useful for improving stress management include meditation, adequate nutrition and sleep, enhancement of social connectedness, and exercise. More specific interventions must be tailored to the patient’s unique situation; discussion of a number of common issues and possible interventions follows.

Marital problems. The quality of a marriage is a critical variable in health maintenance.³⁴ Couples therapy can be useful when both partners are genuinely interested in making the partnership work. There are many

varieties of couples therapy.³⁵ Some short-term marital therapies that have demonstrated benefit include:

- interpersonal therapy,³⁶ which is particularly useful when one of the partners is depressed;
- cognitive-behavioral therapy,³⁷ and
- emotionally focused therapy.³⁸

Of utmost importance, aside from the method of therapy, is that both partners are comfortable with the choice of therapist. Therefore, when possible, the clinician should develop a referral list of several couples counselors, and strongly encourage the couple to interview several therapists before selecting one.

It is not uncommon for one partner to refuse therapy, or to have an addiction and deny any problem or need for help. In those cases, individual therapy geared to addressing a non-partnered marital relationship can still be helpful. For a client enmeshed in a relationship with an addict, 12-step groups such as Al-Anon and Codependents Anonymous can be very helpful and should be encouraged. Since it is the nature of the addict to isolate the non-addicted partner in the relationship from normal supports, these group approaches offer much needed social connection as well as education about the nature of addiction and its impact on families and couples. It is this author's experience that the nature of the particular addiction is less important than the process of addiction itself (although there certainly are differences in the effects of various addictions). In a community with a limited variety of 12-step meetings, the nature of the addiction should not preclude a referral to a 12-step group, even if it is not specific to the patient's situation.

Job stresses may be caused by a variety of factors, including threatened loss of job; interpersonal conflicts; mismatch between skills, abilities, and job requirements; shift work; and physical/environmental factors (e.g. sick building syndrome, lack of adequate breaks, inadequate light, excessive noise). It is important to assess the nature and source of the stressors so that an appropriate plan can be developed. If the client's job is threatened, does the problem reside primarily in the organization, the employee, the industry in general, or some combination thereof? Does the client have difficulty cooperating with others, manifested by a long-term history of employment problems? For that person, individual psychotherapy can be useful in addressing the problem. Sometimes vocational counseling or apti-

tude testing can be helpful when a change in career is being considered, as in the case of an aptitude-skill mismatch. If the situation is such that the client realistically cannot make a change, and has no behavioral options within the situation, then attitude must be addressed and coping strategies devised. This is often best done via cognitive-behavioral therapy.³⁹ Spiritual work on the meaning of the situation can also be beneficial, if the person is so inclined, as can increased attention to other rewarding aspects of life such as hobbies (which can make use of untapped abilities), community work, and satisfying relationships.

Shift work can be a significant stress for many people.⁴⁰ Patients may need to be educated as to the health consequences of shift work, which include increased risk of cardiovascular, gastrointestinal, and reproductive dysfunction as well as depression or exacerbation of other psychiatric conditions.⁴¹ Support from the physician may aid in reducing shift work as much as possible; this can take the form of letters to the employer recommending limits on hours worked or case loads, and emphasizing the medical necessity of such recommendations. If the shift work is continuous, light therapy may be useful.⁴²

Finances. Finances are often a very powerful stressor for clients, not only because of the realities of financial hardship, but also because in the United States the link between financial status, social status, and self esteem reflects our strongly material orientation. Patients may be as reluctant to talk about their finances as they are about their sexual habits. If the client has identified this as an area of stress, approaching the subject with some open-ended questions can be helpful. "When you think about your finances, what do you feel?" Note that the answer to this question should be one or two words, i.e., angry, scared, nervous, sad, not an analysis of the situation (which involves thoughts, rather than feelings). Responses that begin with "I feel *that* ..." mean it's important to restate and clarify the question. Explain that a feeling is usually one word: happy, anxious, tense, etc. Other useful questions on this subject include: "How often do you worry about your finances and have these feelings?" "Does your worry affect your sleep or appetite?" "Do you share these worries with anyone?" "How long have you been preoccupied with your finances?" "Has your financial situation changed and, if so, when?" "What have you tried to do about your situation?" "Have

you sought any help?” “Are you doing the things you need to do?”

Many people with depression and anxiety disorders have unrealistic or exaggerated fears of financial decline. If you are concerned that this may be the case, getting collateral history from a trusted partner, parent, sibling, or caretaker, can be surprisingly useful. If it appears that the patient is unnecessarily anxious, cognitive-behavioral therapy is indicated, and the question of a depressive or anxiety disorder should be raised and explored. It is not uncommon for patients with a depressive disorder to contemplate suicide, hoping that the life insurance payment will alleviate the financial burdens of the family. This factor must be identified and given serious weight in assessment of the depressed or anxious patient who has financial concerns.

If the client is indeed under genuine financial stress, then the physician should consider making a referral to a financial counselor, or a credit repair company. People under chronic financial stress need a strategic plan of attack. They may lack the skills, prefer to avoid the overwhelming feelings of failure and loss of control, or perhaps are simply too fatigued or anxious to develop one on their own. Connecting with a qualified advisor who can guide the development of a sound financial plan can help patients regain a sense of control over the situation, which will reduce the perceived stress. In the course of the discussion, it can be useful to have the client list any possible sources of help that he or she might have overlooked (e.g., friends with financial experience).

Certain stages in life indeed are more financially taxing than others, and the experienced clinician may be comfortable in simply offering support and comfort (“Don’t worry, it will pass. Every one goes through this at one time or another”). But this should not be done until the nature of the problem is clear. Incorrectly used, before a careful assessment of the realities, reassurance can be experienced as invalidating, or a minimization of the problem, with an implication that the client is “wrong” for feeling what he/she does. For patients who are very stressed, such an experience can become a significant barrier to good communications. When asked about the financial problems at the next visit, the patient may indicate that they have been handled, but this assurance may soon be followed by the patient’s disappearance from the physician’s practice, or by a decrease in compliance.

Death of a close relative or loved one. The death of a close relative, friend, or pet often creates stress on multiple levels. The effect of such loss depends on the degree and nature of involvement with the deceased, the nature and quality of the relationship, the manner of and preparation for the death, and the spiritual questions raised by the death. Grief counselors often assume that recovery from loss requires a period of grief work in which the ultimate goal is the dissolution of the attachment bond to the deceased. However, reviews appearing in the 1980s noted a surprising absence of empirical support for this view.⁴³ In fact, different cultures cope with death differently. Rather than detachment from the deceased, some cultures emphasize “transformations of attachment to the deceased.”⁴⁴ Thus the clinician’s role is to identify the grief state, differentiate it from depression, and help the client obtain culturally specific and appropriate support and reintegration into life, in the context of a warm and genuinely empathic concern.

Once the client has identified a loss, the clinician may ask any of the following questions to assess the extent of the impact:

- How long ago did the loss occur?
- How much, how often, and in what ways is this loss affecting you?
- Was the deceased part of your everyday life?
- What was the quality of your relationship? (Ambivalent, conflict-laden relationships are more difficult to grieve.)
- What have your previous reactions been to losses such as these?

These questions will alert the clinician to the degree of recovery from the loss, and the likelihood of a difficult recovery.

In order to differentiate grief from depression, a number of questions must be asked.

- Are you feeling primarily sad, or do you feel depressed or hopeless?
- Do these feelings come in waves, triggered by some memory of the deceased or are the feelings more constant?
- Do you find yourself focused on the deceased and missing him/her, or do you find yourself thinking more about yourself, and your future and past?
- Have you thought that you would like to join the deceased soon?
- Are you able to sleep and eat?

- Is it difficult to engage in your normal activities?
- Are you still able to experience pleasure from the activities you used to enjoy?

If the clinician is satisfied that the client is grieving and not depressed, then a referral to a grief counselor or a pastoral counselor or clergy may be appropriate. If there is an aspect of depression, then appropriate treatment of the depression should be instituted.

Illness. Illness is a stress; it can have many different manifestations in a patient's life: pain, limitations on normal functioning, impact on financial stability or self concept, changes in relationships with others, and the raising of religious, spiritual, or existential questions. Because illness has the capacity to affect one's life in such a pervasive manner, most patients will acknowledge this "burden of illness" as a stress in and of itself. When approached about these issues in a thoughtful manner (and from a functional medicine perspective), many patients immediately experience a reduction in stress because they feel that their problem is being taken seriously and underlying causes are being sought. Many patients are relieved that "pills are not being thrown at me."

The clinician, by virtue of his/her careful empathic interest, restores hope in recovery, and can assist the client in adapting to non-reversible physical changes via support groups, education, and collateral services as needed. It is also part of the practitioner's mission to remind the patient that the goal of all health care is recovery of a vibrant life, with abundant joy and happiness. Achieving this goal is both a privilege and a gift which we as healthcare providers can and must aspire to.

Even brief attention to these factors in the lives of our patients—and to the rapidly developing body of stress research—allows one to appreciate the importance of the contextual soup within which we all live, and with which our stress response systems must cope. Understanding this, it becomes important to take into account additional contextual factors that often impact health via the stress response system: community and socioeconomic status.

Community and Socioeconomic Status

While the precise definition of "neighborhood" is yet to be determined, numerous studies have found that neighborhood context, or "place," does play a role in quality of health.⁴⁵ Neighborhood context has been

investigated as a factor in various aspects of health, including child development,⁴⁶ child problem behavior,⁴⁷ cardiovascular disease,^{48,49,50,51} cigarette smoking,⁵² mental health,⁵³ and overall mortality.⁵⁴ It is intuitively obvious that a community which fosters a sense of control (e.g., personal safety, good visibility, predictability), access to privacy, social support, and access to nature and other positive recreational activities would be one that fosters health. Segregating out the various factors that contribute to the effects of community and socioeconomic status (SES) on health remains a challenge,⁵⁵ yet it is clear that socioeconomic status (usually determined by education, occupation, and income) is also a major contributor to differential health outcomes in various neighborhoods.^{56,57,58,59} The adverse health effects of socioeconomic position are not limited to those at the poverty level, however. In fact, the effects of social position occur at all levels of the social class hierarchy.⁶⁰ This is not surprising when we realize that our position in the social hierarchy determines the degree of control we have (or think we have) over our environment. That sense of control is related to our emotional state,⁶¹ and our emotional state is the "crucial driving force in a chain of events leading from psychosocial interaction to neuroendocrine changes."⁶² These neuroendocrine changes involve the HPA axis (see discussion in Chapter 32) and involve learned expectations of helplessness.⁶³

In the attempt to determine which aspects of SES and neighborhoods most affect health, and to what degree, consideration has been given to perception of the physical environment,⁶⁴ work conditions, housing, municipal services (e.g., transportation, healthcare facilities), community norms and values, social support networks, and political empowerment as components of the impact of neighborhood context on health.⁶⁵ The mediating factors that help reduce morbidity and mortality via higher socioeconomic status are thought to vary with locale and time (e.g., higher SES is a factor in reduced exposure to infection in underdeveloped countries). Diet, nutrition, smoking, exercise, pathogen and carcinogen exposure, crime, and psychosocial factors are also significant areas of concern.⁶⁶

The above-mentioned factors (e.g., neighborhood, perception of relative status, factors associated with poverty) are contextual, yet they operate ultimately at the level of the individual to impact health outcomes. Evidence is accumulating that there are multiple path-

ways by which neighborhood, poverty, and SES determine health outcomes:

- involvement of the stress response system as a result of cognitive appraisal of potential helplessness or harm (e.g., low job control),
- direct effect of health behaviors (e.g., diet, exercise, smoking),
- neighborhood effects (e.g., availability of municipal services, physical perceptions of neighborhood), and
- social support.

Given that socioeconomic status (as measured by education, occupation and income) and community (physical environment,⁶⁷ work conditions, housing, municipal services such as healthcare facilities, community norms and values, social support networks, and political empowerment) must play some role in health, the question arises: How is the practitioner of functional medicine to take these variables into consideration?

The answer to this question varies with the context within which the clinician practices. A patient population of upper income clients, for example, is likely to experience fewer issues of social hierarchy relative to the general population. Practitioners should remember, however, that high SES individuals must cope with many other major stressors, most of which are independent of position: illness, loss of a loved one, job problems, marital and family issues. Financial difficulties such as excessive debt and possible bankruptcy may also arise, and high SES patients may be less likely to admit them due to their perceived social stigma. Clients from very wealthy communities may labor under pressure to maintain their socioeconomic status and lifestyle, which is often a gauge of self esteem.

Populations with narrower income variability tend to have lower mortality rates.⁶⁸ This implies that health-care practitioners should find out who the client compares him/herself to, and where she/he stands in the hierarchy. The impact of social status on health is determined more by perception and personal expectations than by facts. Lacking well-validated instruments, the following questions might serve as a starting point for an analysis of the **patient's perception of socioeconomic status**:

- Do you feel that the people in your life are generally more or less well off than you are?

- If you imagined a scale of 0 to 100, with 100 being the people you know who are most successful in their work and their lifestyle, where are you, currently, in your estimation? Is that a change?
- Are you satisfied with this, or do you feel bad about this sometimes?
- Where do you expect you will be on this scale in the future?

Education is easily assessed with a few straightforward questions:

- What is the highest degree you have attained?
- Are you satisfied with this, or do you feel this holds you back?
- Do you intend to get further education of any type?

Occupation may require a little more probing. Asking "What kind of work do you do?" might generate a response such as, "I work at ABC accounting corporation." The practitioner might accept this answer, but still not know whether the patient is a janitor, a clerk, an accountant, a partner, an administrator, a salesperson, or in human resources. Does he/she like what he/she does? If not, why not? Aptitude testing (to determine a more appropriate career path or job), along with skills training and work on interpersonal skills, might be important; a job change may need to be considered.

The physical environment one lives, works, and recreates in can have significant effects on all aspects of health. The biological (e.g., sanitation, water quality), psychological (crowding, privacy), social (safety, neighbors, local services), and aesthetic (trees, flowers, design, open space) aspects of community are all important. For example, a recent study of 207 elderly people living independently indicated that "a considerable number of the residents in the Silver Peer Housing facilities studied had mental health problems associated with limitations in the layout of their apartment and/or the location of the housing."⁶⁹ Practitioners who are able to make house calls (or otherwise become familiar with the cultures and communities their patients inhabit) have an advantage both in connecting with the client and in avoiding the pitfalls of making unreasonable healthcare suggestions. Asking a patient to "jog or walk around your neighborhood," without knowing whether there are concerns about crime, traffic, or air quality may be a mistake. The amount of sunlight exposure (affecting vitamin D levels and possibly seasonal affective disorder), ventilation and air quality, noise

exposure affecting sleep-wake cycles (e.g., 4 am street cleaners, airplanes overhead), and access to nature are additional variables to consider. The amount of perceived control over one's environment can reinforce a sense of optimism or despair.

As practitioners, we must consider the **cultural norms** that drive behavior. Each community has particular characteristics with which the practitioner can become acquainted. In higher SES communities, it might be the norm to have a drink at lunch or half a bottle of wine with dinner. Immigrant or ethnic communities may connect very closely with particular foods; as we know, diet has a powerful impact on health. To elicit some of these factors, patients can be asked to identify potential obstacles to dietary or lifestyle changes they might face within their families, at work, or in their communities.

Social support networks should be assessed; questions such as the following are useful:

- Do you feel isolated or lonely?
- How well do you feel you fit in with your community?
- Where do the different members of your family live?
- Who are you closest to in your family? Where do they live? How often do you speak to or see them?
- Do you generally feel better after a visit with certain members of your family?
- When you have a problem, who do you turn to?
- What kind of friendships do you have? Are they of long or short duration?
- Have you suffered any losses of important people?
- Who do you have fun with?

Political empowerment can be defined as feeling able to influence the political events and economic decisions that affect one's community. A community with low levels of political power will suffer health consequences on a broad scale. Clinicians who empower their clients to be in charge of their health can diminish the helplessness that members of disenfranchised communities often feel. Beyond the individual level, however, there are several other factors to consider. The practitioner who works in a lower SES community might consider connecting with influential individuals within the community (e.g., the pastor of a local church) to advance educational efforts (e.g., nutrition, fitness, or general health promotion programs for ado-

lescents) that have the potential to reach a larger number of people in a more fundamental manner than can be achieved one-on-one.

The Impact of Spirituality and/or Religion on Health

Defining Spirituality and Religion

Over the past 15 years, there has been increasing interest on the part of both patients and healthcare professionals regarding the role of religion and spirituality in the promotion of health.^{70,71} While definitions of spirituality and religious practice overlap significantly, they are not interchangeable terms. Spirituality and religion are best thought of as two overlapping circles in a Venn diagram.⁷² Spirituality can be defined as the search for the sacred, the sense of being connected to something greater than self, while religion may be defined as an organized, institutionalized, social mechanism for attaining the spiritual connection.

Relevance of Spirituality and Religion to Healthcare Practitioners

Human beings receive information about the world in three ways: from the food and water we ingest, from the air we breathe, and via our senses (conscious or unconscious experience, observation, and interpretation of the world and ourselves). These inputs impact the expression of our genes via complex interactive pathways. If we turn our attention to the third pathway, the senses, we recognize that the sensory input we receive is constantly evaluated by our mind and body, so that we may respond appropriately. There is an ongoing automatic and preconscious inner dialogue, so to speak: "Is this chair comfortable?" "Do I trust this person?" "Am I in danger?"

One primary filter through which we evaluate incoming sensory input is our set of beliefs and attitudes (cortical function); another is our limbic (emotional) predisposition. Support for the proposition that thinking affects emotion comes from Beck,⁷³ who, in formulating cognitive-behavioral theory, postulated that one's views of self, the world, and the future (the "cognitive triad") are critical determinants of one's emotional state. Numerous studies have demonstrated the effectiveness of cognitive therapy in a variety of psychiatric disorders.^{74,75,76,77}

Furthermore, according to Schore,⁷⁸ “Because the right hemisphere of the brain is deeply connected into the limbic system and the autonomic nervous system, it is centrally involved in controlling vital functions supporting survival and enabling the individual to cope with stresses and challenges.” Thus our automatic and rapid assessment of sensory input may be negative, neutral, or positive, but the valence of the interpretation we place on our experience is then conveyed to the deeper brain structures such as the amygdala, the hippocampus, the hypothalamic-pituitary-hormonal axes, the autonomic nervous system, the immune system,⁷⁹ and other points on the functional medicine matrix. Given a favorable assessment of sensory input, we experience pleasant feelings, such as pleasure or relief, and a corresponding physiology. A negative assessment activates a different psychophysiological response.

It is thus reasonable to conclude that the separation of mind-body that has pervaded western medicine is unfounded.⁸⁰ The mind-body is, in fact, an interactive single unit embedded in the larger sociocultural environmental context. Beliefs and attitudes can influence the entire state of the person, including physiology. Thus, religiosity and spiritual beliefs are vital issues in health promotion and are addressed within the functional medicine matrix. Body and mind are inextricably intertwined. Acknowledging these facts, researchers have sought to determine and define the effects of spirituality and religion on health.

The Evidence Concerning Health Effects of Spirituality and Religion

In a comprehensive and systematic 2001 review of the literature over the past century, Koenig assessed over 225 reports on religion and pain/disability, heart disease, blood pressure, stroke, immune/neuroendocrine function, infectious disease, cancer, and overall mortality.⁸¹ He concluded that:

While more research and better designed studies are needed, the vast majority of research completed to date indicates that religious beliefs and practices are associated with better mental and physical health. These associations are as consistent and robust as associations between health status and other psychosocial variables (like social support, marital status, and certain health behaviors).

In another critical review of the evidence, which differentially assessed religious/spiritual dimensions and meditation/relaxation, Seeman et al.⁸² created a “levels

of evidence” ranking system to evaluate the available literature. Studies were ranked according to the strength of study design (A to C). Eleven propositions relating to the hypothesized relationships between spirituality/religion and physiological markers (e.g., blood pressure, oxidative stress) were then developed. They defined four levels of evidence:

- 3 (persuasive support for the proposition, including at least three category A studies),
- 2 (reasonable evidence demonstrated by two category A studies or 3–4 category A and B studies),
- 1 (some evidence in at least one category A study, or two or more category B studies), and
- 0 (insufficient support, i.e., not even one category A or two category B studies to support the proposition).

They concluded that:

1. Meditation/relaxation is associated with better health outcomes in clinical patient populations (category 3).
2. Meditation/relaxation is associated with lower blood pressure (category 2.5).
3. Religion/spirituality is associated with lower blood pressure, less hypertension, better immune function (all category 2).
4. Meditation/relaxation is associated with lower cholesterol, lower stress hormone levels, and differential patterns of brain activity (category 2).
5. Meditation is associated with less oxidative stress, and less blood pressure and stress hormone reactivity under challenge (category 1).

In contrast to these reviews, Sloan et al.,⁸³ in a comprehensive “though not systematic” earlier review of the empirical evidence, raised the flag of caution. While he acknowledged the great interest in the subject at hand, he pointed out that the quality of the research is marred by inadequate definition of terms, poor control of confounding variables and other covariates, a failure to control for multiple comparisons, and conflicting findings. He raised concerns about the ethical validity of intervening in a patient’s life with a “non-medical agenda,” and described it as an abuse of professional status. Even if religious or spiritual factors are determined to be related to health outcome, he contended that “we generally regard financial and marital matters as private and personal and not the business of medicine even if they have health implications.” He therefore advocated that the

religious/spiritual should remain in that private domain. Finally, he expressed concerns that “linking religious activities and better health outcomes can be harmful to patients, who already must confront the age-old folk wisdom that illness is due to their own moral failure.”

In response to Sloan, Powell et al.⁸⁴ conducted another “levels of evidence” approach to the question in 2003. This review specifically excluded studies examining the link between religion or spirituality and physiological markers (e.g., blood pressure), studies examining all psychosocial outcomes (including suicide, substance abuse and depression), and studies with a variety of methodological flaws. Powell et al. concluded that while a relationship between religion or spirituality and physical health exists, it may be both more limited and more complex than some authors suggest.

Among their findings:

1. In healthy individuals (especially females) there is a dose-response correlation, where frequency of church attendance is positively correlated with approximately 25% reduction in mortality, after adjustment for demographic, socioeconomic, and health-related confounders (e.g., better diet in attenders).
2. There is inadequate support for the hypothesis that religiosity protects against disability.
3. While there is a positive correlation between weekly church attendance and reduced cardiovascular disease (myocardial infarction, angina pectoris, stroke, congestive heart failure, and congenital cardiovascular defects), a large measure of the relationship is accounted for by the healthier lifestyles adopted by churchgoers. Given the difficulty maintaining long-term lifestyle change (see section on promoting lifestyle change) by other methods, these data do support encouraging church attendance as one method of improving lifestyle factors that contribute to morbidity.
4. All five studies that qualified for review failed to support the hypothesis that religion or spirituality improves objective measures of recovery from acute illness. Three qualifying studies of intercessory prayer (prayer at a distance), although not without flaws, indicate that being prayed for improves the quality of the subjective experience during recovery from acute illness.

Integrating Spirituality in Clinical Practice

As the popular pendulum swings toward the perception of spirituality as a legitimate health-promoting factor, it is simultaneously becoming clear that facile conclusions are unwarranted and that many voids in our knowledge base remain. In the face of these cross-currents, clinicians are at the helm, obliged to navigate complex waters as clients, media, and the professional literature demonstrate increasing concern and curiosity.⁸⁵ For those practitioners who plan to integrate this important aspect of health into clinical practice, there are some key issues to consider:

When can the clinician know that a discussion of religion or spirituality is indicated? Given the trend of the data, which indicate that there is some degree and nature of interaction between religion/spirituality and health, it seems prudent to assess this factor as a point for potential intervention in the majority of patients. In the treatment of chronic diseases, the approach must be individually tailored. The clinician should determine the relative importance the patient places on the subject matter, and assess the receptivity of the patient to the issue, while asking him/herself, for example, whether the relationship between the patient and healthcare provider can “hold” the subject. The majority of the American population would welcome their physician’s inquiry into their spiritual or religious practice if gravely ill.⁸⁶

How does one explore the subject? On the front lines of medicine, statistics can only offer probabilities, and each patient must be recognized as unique. From this perspective, we might open the subject with a simple inquiry: “Mr. Jones, is spirituality or religion important to you? Is it something you would like to discuss, with me or with someone else?” In the case of a patient with chronic stress, hypertension, perhaps immune dysfunction, or an imbalance of adrenal function (such as low morning cortisol), meditation or relaxation techniques might be offered as a tool for addressing the patient’s physical problems.¹ “Development of a daily meditation

¹There are many approaches to meditation or other relaxation techniques; some clearly have a spiritual or religious connection, while others do not. It may be important to the patient to know more about those nuances. Resources are usually available in most communities, but *Full Catastrophe Living* (Jon Kabat-Zinn) outlines a structured meditation program, and is an excellent book. A less structured approach to meditation is discussed in Jon Kabat-Zinn’s second book, *Wherever You Go, There You Are*. Tapes can be purchased to facilitate the learning on one’s own, although live training and group practice may help patients learn the techniques more quickly and effectively.

practice, has been shown to be very helpful for many people, Ms. Jones, so that when you are stressed you will manage it better.” If meditation is recommended, it should be emphasized that this is a skill that takes time to develop, but one which can have many health benefits, both mental and physical. In a patient who is depressed and/or guilt ridden, meditation (during which he/she may ruminate on negative cognitions) could be contraindicated. Similarly, I have seen religious attendance be helpful as well as harmful. In cases of trauma or guilt associated with a specific church, the clinician could support the patient’s exploring other religious denominations (if the patient is so inclined).

After ascertaining whether the patient is religiously or spiritually oriented, you may want to define the difference between the two, so the patient is clear about the question. It’s also important to evaluate the clinician’s context—i.e., what is the nature of your relationship to the patient? Are you (the clinician) pursuing a spiritual or religious practice? Has it been helpful with your personal health issues? Do you have any negative feelings/experiences associated with religion or spirituality (e.g., being forced to go to church, abuse history within the church)? It may be appropriate to make a personal disclosure about the role of religion or spirituality in one’s own life, if the relationship with the client can hold the disclosure: “Self disclosure on the analyst’s part facilitates self disclosure by the patient, and therefore productive dialectical interchange between analyst and patient is maximized.”⁸⁷

What are the risks of raising the subject? Clinicians must approach the assessment of spirituality/religion with respect for the patient’s autonomy, personal history, and social context. The inquiry must remain as neutral and non-judgmental as it is for any other area of inquiry. The sole goal of the inquiry must be to benefit the person’s health. The clinician must be sensitive to the patient’s inclinations, and conduct the discussion with respect and sensitivity. If the clinician detects resistance to the subject matter, it is very important to acknowledge the person’s right not to discuss the issue, and simply let them know that, should they desire to discuss the issue in the future, the door will be open. Failure to approach the person in this manner has a high likelihood of eroding the foundation of trust in the relationship.

Where/how to set the boundary between the clinician’s belief system and that of the patient can be tricky.

Generally speaking, the boundary will be a function of the interaction between the clinician’s belief systems and the patient’s belief systems, and the clinician’s function is, first, to protect the patient and, second, to guide him/her if such guidance is desired. As in all areas of clinical practice, there is a somewhat porous, interactive boundary between the physician’s life, beliefs, personal history, personality style, and those same factors within the patient. Clinicians who eat properly and exercise may be more likely to focus on such issues with their patients. Consequently, a physician who manifests some mastery of these lifestyle factors can be perceived as supportive and hope-inducing by some patients; yet, for other patients, the clinician’s mastery may paradoxically represent a mirror of their own imperfections. Each clinician-client interaction presents a unique interactive dynamic, a human chemical reaction. So, a clinician who considers him/herself atheist will have a different interaction with a very spiritual patient than a clinician who is him/herself very spiritually oriented. It’s important to be cognizant of this interactive tension, which can be communicated by many nonverbal factors, ranging from body language to office decor.

On the other hand, a clinician-patient dyad in which both parties are members of the same religious persuasion, and perhaps of the same community, offers different potential benefits, perils, and outcomes. The clinician must therefore understand that there is no formulaic approach in this arena, and it is most important that general principles of autonomy, respect, sensitivity, and care are the clinician’s guideposts.

How does the clinician establish an effective referral to a pastor or other trusted person? Once the client has indicated the desire for further discussion or exploration of the spiritual/religious realm, the clinician should help the patient determine with more precision what the needs are. If the patient is confused about allegiance to a church, referral to a pastor might be less useful and more threatening than referral to a pastoral counselor, who is trained in both the spiritual and psychological dimensions. Is the client looking for a new pastor or for training in meditation? Possibly a new religious community or a support group might be needed. As clinicians become more skilled and informed, it can be very useful to develop a resource list and a bibliography that can be offered to those who are interested. The best strategy is to address the client’s needs with suggestions about resources they may have

overlooked. Once these needs have been identified and a plan for action has been determined, the clinician may offer to make the initial contact (a referral) on the patient's behalf. Finally, follow up should be done on the next visit with an inquiry as to action and outcome.

What clinical outcomes can the clinician and patient expect? Because “very little apparent progress has been made within the health promotion/health education discipline [on] the development of integrated content, methods, and applications for spiritual health promotion,”⁸⁸ clinicians must extrapolate to determine the best methods of promoting health and setting reasonable expectations for outcome. Inadequate information also exists in other areas of healthcare, where clinicians must often make decisions without full information. The data seem to support the assumption that the earlier one intervenes in the multicausal chain of illness, the more beneficial the effects. Powell observed that “the effects of prayer and meditation may be more powerful in the prevention of mortality before the overwhelming force of functional impairment sets in.”⁸⁹ Early life stresses as well as chronic stress result in isolation, helplessness, and consequent adoption of unhealthy lifestyles (e.g., poor diet, smoking, lowered activity levels). These lifestyle habits then interact with genetic predispositions, mediators, and triggers, resulting in disease. After a comprehensive literature survey, Hawks⁹⁰ reviewed three peer-reviewed, well-designed, reproducible, spiritually-based, comprehensive health intervention programs (the Lifestyle Heart Trial, a Stanford University School of Medicine complex psychosocial intervention in patients with metastatic breast cancer, and the stress reduction clinic of Jon Kabat-Zinn at the University of Massachusetts Medical Center). The Hawks concluded that:

... improved spiritual health may be associated with improved behavioral and emotional health in such areas as diet, activity levels, communication skills, treatment compliance, reduced anxiety and depression, and improved mood states. These positive behavioral and emotional improvements in turn may be associated with heart disease reversal, reduced cancer mortality, enhanced immune function, and reductions in pain and other medical symptoms.

Mind-Body Interventions in Clinical Practice

This brief review of health effects of certain mind-body factors—stress, religion and spirituality, commu-

nity and poverty—indicates the complexity of the field and the multiplicity of issues that may play a role in health outcomes. It is abundantly clear that each aspect of the bio-psycho-social-spiritual web is interactive and in communication with other aspects. Much remains to be clarified before definitive guidance can be offered by the research community. What is the clinician to do?

First Things First

The practitioner's choices will be dependent, in part, on the type of clinical setting and the resources available to both clinician and client. Clinicians who practice in a private setting can “provide health education advice to individual patients, whereas clinicians in community health centers are more likely to be involved in group health promotion activities and broader community development initiatives.”⁹¹ The functional medicine practitioner needs to determine, first, how, and to what depth, he/she will be integrating this material into clinical practice. That assessment will affect the setting and style of practice, as well as the potential activities that can be integrated.

Helping Patients to Change

Next, it is good to have an awareness of the factors involved in making permanent behavior change. While it is frequently possible to assist patients in making short-term changes in lifestyle factors known to promote health (e.g., improvement of diet, addition of meditation and exercise, etc.), it is far more challenging to promote long-term lifestyle change. Recognizing this fact, in January of 2003, the National Institutes of Health, Office of Behavioral and Social Sciences Research targeted funds toward the study of factors involved in the maintenance of long-term behavioral change.⁹² While clinicians wait for the results of this research initiative, certain guidelines can tentatively be suggested.

From the clinician's perspective, it is best to view change as a long-term process, involving different stages of both change and relapse. “Behavior change is rarely a discrete, single event; the patient moves gradually from being uninterested (pre-contemplation stage of change) to considering a change (contemplation stage) to deciding and preparing to make a change.”⁹³ These stages are followed by the active change phase and then maintenance of change. Most people find themselves “cycling through” the stages of change sev-

eral times (relapsing) before the change becomes truly established. A detailed discussion of the stages of change approach is provided in Chapter 36.

Emphasizing the fact that long-term change requires long-term support and follow-up, a randomized five-year outcome study of the effect of dietary change and smoking reduction in patients with angina revealed that changes were sustained at two years, but not at five years.⁹⁴ The intervention group received two years of quarterly personal health promotion from a trained nurse. This study highlights both the efficacy of short-term interventions, and the unanswered questions about induction of long-term change.

Short-term Studies of Health Promotion

Successful intervention on the nutritional level can have broad-ranging benefits on health outcomes. In a systematic and thorough review of published information on methods to change key dietary habits (fat, fiber, and fruit and vegetable intake), Bowen and Beresford⁹⁵ focused on interventions at the individual level, the family/provider, worksite interventions, and community level. Multiple studies in their review indicated that nutritional counseling, individually or in group settings, can have sustained impact on nutritional status at one year following intervention.

Another one-year follow-up reported in 2003 used biomarkers of dietary change (e.g., plasma beta carotene) to measure outcome.⁹⁶ This study supported the hypothesis that brief interventions (two 15-minute sessions, two weeks apart, supported by written materials and consisting of either behavioral or generalized nutritional counseling) can be an effective means of increasing consumption of fruits and vegetables. The behavioral intervention (which was statistically more effective in changing the biomarkers than the generalized nutritional counseling approach) was based on the “stages of change model.”⁹⁷ The intervention was tailored to which stage of change the subject was considered to be in (i.e., precontemplation, contemplation, preparation for change, action, or maintenance). This individualized approach was found to be superior to the generalized nutritional approach (which pointed out the importance of healthful diet, the constituents of a nutritionally sound diet, and the effects on health). Interestingly, the effects of the interventions were similar across income groups. Based on this study, clinicians might consider assessing the cli-

ent’s stage of change before intervening, with the intention of offering stage-appropriate advice.

In a survey of 796 low-income people, Eikenberry and Smith⁹⁸ provided evidence that low-income individuals lack knowledge of what constitutes a healthful diet, that racial and economic differences exist in motivation for eating well (African Americans and lower-income individuals had less motivation), and that time and money were cited as the most significant barriers to healthful eating. The most common promoters of healthful eating were social factors (living alone was a frequent barrier; how one was raised was also influential) and food assistance programs. Based on this survey, and the common-sense notion that eating is generally a social activity, clinicians might consider promoting increased (or at least regular) frequency of family meals. Encouraging patients to reconnect with their cultural cuisine might be an additional incentive for some individuals to steer away from fast food, and move toward a more wholesome and meaningful diet; this might also enhance a sense of connectedness to a larger community. For adolescents, family meals can have a marked influence on a variety of behaviors. “In general, adolescents who reported more frequent family meals, high priority for family meals, a positive atmosphere at family meals, and a more structured family meal environment were less likely to engage in disordered eating.”⁹⁹ Frequency of family meals has been positively correlated with reduced substance use, academic performance, self esteem, depressive symptoms, suicidal ideation, and suicide attempts.¹⁰⁰

Similar results were reported from a short-term intervention for behavior change directed at reduction of cardiovascular risk factors;¹⁰¹ however, due to the short duration of the intervention, the actual risk levels were not changed (with the exception of blood pressure), despite changes in behavior.

In an evidence-based review of physical activity promotion, Eakin, Glasgow and Riley¹⁰² found that “well controlled physical activity studies have generally produced moderate short-term improvements, but these results are often less encouraging at long-term follow-up. Of significant note is the fact that all except two of the 15 studies that met the criteria for review relied on self reports of physical activity, although the two studies that used objective measures (e.g., activity monitors) corroborated the self reports. In addition there was considerable variability across studies.” Physical

activity-only interventions fared better in the short term, but all three of the studies with significant long-term effects were multiple risk factor interventions (e.g., diet/exercise/smoking). While conclusions are certainly premature, this could imply that long-term change is best achieved by approaching the patient's life with a broad lens. A program that utilizes multiple interventions and recognizes the whole person, including social and occupational contexts, as well as stages of change, might be most useful. Clinicians can expect significant failure rates from any approach they employ, as study attrition rates were 20–56% in the longer-term follow ups. Not surprisingly, those in poorer health, those with less education, and smokers were more likely to drop out of the studies.

Long-term Studies of Health Promotion

A more recent review of physical activity promotion studies,¹⁰³ using similar exclusion criteria (the RE-AIM model¹⁰⁴), indicated that five out of nine long-term studies (six-month follow up or longer) reported positive findings for a variety of interventions (e.g., physician/nurse counseling, written materials, mailings, and telephone follow-up), varying frequency, and duration of contact. This report concludes that “the evidence about the long-term impact of single risk factor interventions and about the effect of multiple risk factor interventions” is equivocal. There is good evidence that “interventions delivered to primary care patients that address physical activity alone can achieve short-term” changes in physical activity. The author recommends that clinicians “carry out brief interventions to advise patients with health problems who could benefit from increased physical activity.” (An extensive review of the health effects of increased physical activity is available in Chapter 13; Chapter 29 offers a detailed discussion of how to help patients plan and implement a physical fitness program.) In clinical practice, the clinician must follow up, at each visit, on the targeted behavioral changes, which should be prominently displayed in the patient's chart or problem list. When dealing with chronic health problems, long-term changes in health-inducing behaviors require long-term concern, monitoring, encouragement, positive reinforcement, and problem solving on the part of both clinician and client.

Summary

This review of the effects of spirituality, community, poverty, and stress on health indicates that much more research is called for to help us understand the influence of these factors on patient (and population) health. We do know, however, that there can be significant health effects, that these are complex variables, and that they are in all likelihood linked inextricably with the larger societal context within which people live. Our current system is making slow progress in quantifying factors and variables that affect quality of life and health status, but the evidence-based recommendations offer only broad guidelines. These facts make broad-based, one-size-fits-all suggestions difficult and inappropriate. Fortunately, several themes emerge from the data, to help the practitioner who wishes to expand her/his clinical practice to include direct attention to mind-body factors.

Interventions must be individualized. Individualization of care requires that we obtain more information about our patients' lives. Clinicians must find ways to acquire knowledge that, in the past, was often gained by the house call (“Hey Joe, I don't like what I am seeing in your refrigerator”). Thinking outside the box (a picture is worth a thousand words), one might ask patients for pictures of their home, their kitchen, etc. Fundamental questions must be asked: Who exactly is in the patient's intimate social network? How much contact with them are they able to have? What does their home and neighborhood look and feel like to them? What are the patient's social and personal barriers to improving specific health behaviors? What is the patient's financial situation? How does the patient feel about religion or spirituality? How does the patient experience and cope with stress (are symptoms felt in the mind, the body, or both)?

Some sort of partnership with the patient must be formed. Many patients, but certainly not all, prefer to be involved in the clinical decision-making process.^{105,106} As patients age, they want more interest from their healthcare providers regarding health care.¹⁰⁷

Clinicians must be realistic about what they can expect of themselves and of their clients. These expectations should be contingent on the setting and skills of the practitioner and the life setting of the client. Expectation of behavioral change must be tempered by an understanding of the long-term nature of that pro-

cess, and various interventions must be tried, seeking a suitable and personalized approach for each client.

Finally, healthcare practitioners must strive to form caring, warm, empathic, genuine relationships with their clients. The clinician-patient dyad can be considered, like most relationships, a third entity that grows over time, out of the affinity that the parties develop for each other. This third entity evolves within a socioeconomic and political medium that is different for each client, and often includes a wide variety of influential third parties (e.g., clergy, therapists, insurers, courts, pastoral counselors). The nature of the partnership is influenced by all of these factors. The clinician's availability in times of urgent need can help solidify the partnership, as can genuine empathy, acceptance, warmth, appropriate humor, and a real interest in who the client is in body, mind, and spirit. It is only in the clear air of such a healing relationship that new and healthier behaviors can be nurtured.

Section VII

Putting It All Together

Chapter 34

The Patient's Story; the Clinician's Thinking—A Place to Start

Michael Stone, MD, and David S. Jones, MD

Introduction

Healthcare practitioners—whether modern or ancient, from Western or Eastern disciplines, physician or shaman—have always needed a system for constructing an “explanatory story” of the patient’s illness. These systems can vary from a few questions and much observation (an approach characteristic of the Yupik shaman), or prolonged palpation of the pulse while listening to the breathing pattern (a Tibetan healer), to patient questionnaires accompanied by physical exam and laboratory data (the Western medical model). Whatever the tradition or training, the healer/healthcare practitioner and patient together construct a story; the most comprehensive methods integrate experiences, perceptions, observations, and objective information into a coherent, culturally-sensitive narrative. Two important outcomes are generated from a *comprehensive* patient story: (1) the patient experiences being understood within a context that is often considerably broader than the standard biomedical portrait, and (2) hope is established in the minds of both patient and practitioner that steps can be taken to change the trajectory of the present illness back toward health.

Clinical medicine really begins with the patient’s story, so it is worth our time to be sure we construct that story in a way that is appropriate to the patient, to his or her complaint(s), and to the therapeutics that can be most helpful.

Most healthcare systems have a heuristic approach to this challenge—a shorthand way of directing attention that does not require continuous application of the entire, detailed decision model at every step of the process. Collecting, sorting, and focusing relevant data toward the development of a coherent story and well-founded therapeutic plan can, indeed, be cumbersome and time-consuming in the absence of an efficient model. In standard medical care, efficiency is gained by generating and sorting information through a well-established and very useful model: chief complaint, medical history of the presenting problem(s), past medical history (including important family medical history), social and work history, present medications, history of drug sensitivities, and a complete review of systems. This standard medical heuristic is organized to achieve a relatively quick and highly useful distillation of the patient’s story into a “short list” of potential diagnoses; the process of selecting among those potential diagnoses (achieving the differential diagnosis) is usually facilitated by collecting further data (physical examination, laboratory measures) related to the most likely choices.

The inherent goal in this model is to narrow the inquiry down as quickly as possible to a specific diagnosis,¹ with the expectation that such a process leads fairly directly to a therapeutic plan of (usually) pharmaceutical and/or surgical intervention(s).² Implicit in such a model is a belief that enough of the patient’s full story can be captured by a diagnosis that an appropriate and

effective treatment plan can be based upon it. The organization of information into only those categories that help the clinician formulate the diagnosis and the treatment plan simplifies the process of “doctoring,” and lends coherence and reproducibility to the standard medical approach.

The cost, however, of the speed and efficiency of this model is that the narrow focus precludes a comprehensive response to some of today’s most common and costly conditions: chronic, complex illnesses.³ Speed and efficiency are highly desirable in the acute care setting; however, the steady and disturbing rise in the incidence and prevalence of serious chronic diseases makes the case that those are not the best standards for non-acute circumstances.

This textbook has been devoted to the exposition of a new information-gathering-and-sorting architecture that stands on the very substantial shoulders of the standard medical paradigm, expanding it with an emphasis on principles and mechanisms that weld meaning and mechanistic explanations to the diagnosis, and deepen the clinician’s understanding of the often overlapping ways things “go wrong,” and what to do about it.

Any methodology for constructing a coherent story and an effective therapeutic plan in the context of complex, chronic illness must be flexible and adaptive. Like an accordion file that can compress and expand upon demand, the amount and kind of data needed will necessarily change in accordance with the patient’s situation and the clinician’s time and ability to piece together the underlying threads of dysfunction. In the acute setting, the clinical information requirements contract to a very slim, survival-driven set of points that provide guidance and milestones with as little extraneous information as possible in order to achieve rapid diagnosis and intervention. Relevant examples of the clinical conditions responsive to this model abound: cardiac arrest, gram-negative shock, pneumonia, herpetic corneal infection, spinal cord compression, and so forth. However, in the approach to complex chronic illness, with multiple co-morbidities, the accordion file must expand to incorporate a much larger database of relevant information. For example, the compilation of the “present illness” section of the

history and physical must expand to include a thorough investigation of antecedents, triggers, and mediators (see Chapter 8), if the completed story is to develop and sustain a robust partnership between the patient and the healthcare provider. Personalized medical care without this essential investigation will fall short. There are many pathways that can lead to chronic disease; the story elements must broaden sufficiently to assess those.⁴ Diagnosis is only one step in the functional medicine process; it is not, as it often is in the standard paradigm, the final step before intervention.

Traditionally, the *review of systems* assesses how the various organ systems—neurological, ENT, respiratory, cardiovascular, etc.—are functioning; it follows the questions about present illness and past medical history and often completes the initial data collection process. In the setting of complex, chronic illness, however, a new step must be inserted after the *review of systems*. In order to construct a robust response to the many issues of chronic illness, a “*review of mechanisms*” (functional medicine’s *raison d’être*) must engage the clinician’s attention. (As is apparent from a glance at the functional medicine matrix—discussed below—this process includes the mind-body or psychosocial mechanisms as well as the physical.) This step enables the clinician to engage in a focused review of pathways and factors that contribute to the development and perpetuation of disease. To complete the metaphor, in the *acute medical setting*, the accordion file takes on a compressed, streamlined profile, with non-essential information removed to facilitate rapid response. But in *chronic, complex disease* care, the file expands to accommodate a more comprehensive set of data elements that help the clinician understand a great deal more about the patient: environment, genetic predispositions, physiological and biochemical functionality, and body/mind/spirit influences. The end point of this expanded process is a patient story that is broader and deeper, and that contains many more indicators for both patient and practitioner in terms of developing and implementing an effective therapeutic plan.

The Functional Medicine Matrix or Web

In 1913, William Osler anticipated our ability to “study the interaction of internal secretions, their influence upon development, upon mental process and upon disorders of metabolism.” He believed it would “likely prove of a benefit scarcely less remarkable than that which we have traced in the infectious diseases.”⁵ In recent years, examples of our more sophisticated understanding of human physiology are increasingly part of our common knowledge and clinical thinking—from genetics and the genome to cytochrome P450 polymorphisms, from the symphony of cytokines involved in inflammation to emerging vitamin D research documenting its role as a humoral, immune modulator (a “hormone”). As a result, we now recognize many different opportunities for clinical intervention. Figure 34.1 depicts one way of considering the continuum of health in the functional medicine model.

Methods for helping clinicians incorporate new evidence and new ways of thinking into the pressured pace of clinical practice must be improved. Functional medicine offers an approach to the comprehensive *review of essential elements and mechanisms of disease* that incorporates “the interaction of internal secretions” and the emerging understanding of human physiology and mind-body research. Explicit in the

principles of functional medicine is the concept that each patient comprises his or her own “universe” with a unique set of interconnections, potentials, diversities, and reserve capacities.⁶ Also recognized is that “the body can only be understood as a whole.”⁷ The functional medicine principles (see Section II of this book) add a significant level of complexity to the clinical thinking process, requiring not only more data collection but also a conscious synthesizing process: Who is this patient—in detail and in whole? IFM has developed some tools to facilitate both data collection and sorting, as well as analysis/synthesis. The central organizing tool is the functional medicine *matrix* or web tool (see Figure 34.2). Further on in the chapter, we’ll discuss the use of the matrix, but it’s important to have the basic image in mind at this point.

2010 Update Note: The Functional Medicine Matrix Form and concepts continue to evolve. Throughout most of this book, an older version of the matrix is shown and discussed. In Figure 34.2, however, we show the 2010 version of the matrix, so the reader can examine what has changed. The new cases included in Chapter 37 also show the 2010 version of the matrix form.

—The Editors

Figure 34.2 The Functional Medicine Matrix Form

Understanding the Functional Medicine Model: Comprehensive Care, Part I

Consider a woman in her 60s with a fractured toe. The acute problem is identified, evaluated, and fixed (orthopedically, if necessary) and the patient’s toe heals. Right? This is often true and usually signals the end of standard medical management. However, comprehensive care, even in this apparently simple acute case, encompasses a broader mission; further evaluation might indicate underlying contributory problems, and a preventive approach to those may prevent similar problems in the future.

Asking one basic question initiates a process that could have significant long-term health benefits for the patient: *What were the antecedents to and/or triggers of the problem?* Underlying issues may include bones weakened from vitamin D or mineral undernutrition; medication-nutrient interactions that have altered absorption or excretion of bone matrix substrate; endocrine dysfunction; chronic inflammation; lack of exercise or altered weight bearing; balance or movement problems perhaps

triggered by intoxication; pharmaceuticals or botanicals that may be affecting detoxification. Perhaps the patient was simply clumsy, hurried, or distracted. If so, why? Stress, sleep dysfunction, and mental or emotional distress could all be factors. Organizing a rational process for this more robust investigation will be the focus of the remaining parts of this chapter.

Tools to Assist in Comprehensive History-taking

Before proceeding further with this case, let’s imagine an entire therapeutic encounter. First of all, a critical aspect in the establishment of trust and the creation of a therapeutic alliance is cultural sensitivity to the circumstances and beliefs of the person seeking help (see Chapter 36 for an in-depth discussion on creating effective doctor-patient relationships). How a question is asked can be nearly as important as whether it was asked at all. In gathering information to illuminate the diagnosis and functional assessment, the stage is also being set for downstream issues of compliance with treatment recommendations and alliance in the thera-

peutic relationship. Identifying obstacles to health in the data-gathering process—whether physical, mental, emotional, or environmental—demands conscious attention, skillful interviewing, and effective listening. Table 34.1 reviews common elements of a comprehensive history; most of these points will be familiar to clinicians from many different disciplines, but it's good to have the basic context in mind, because it's what we build upon.

The history-taking can be facilitated by appropriately focused data-collection forms. Every office has these, of course, but we offer in the Appendix samples of a few forms that support a functional medicine approach:

- The *Adult or Child Toxin Exposure Questionnaire* is useful if the patient has a history suggesting drug, nutrient, or environmental intolerance.
- The *Life Stress Questionnaire* will help identify issues that are known to affect emotional stress and health.
- The *3-Day Diet Record* provides a very straightforward way of assessing dietary habits, and it can be reviewed in the context of the healthy eating pyramid⁸ proposed by Walter Willett. This type of record can be used to assess adequacy of diet compared to the old and new USDA food pyramids^{9,10} and the vegetarian food pyramid guidelines,¹¹ as well as other popular diets, all of which have their own strengths and weaknesses.^{12,13}
- Additional useful forms include the *Detailed Review of Systems* and the *Medical Symptoms Questionnaire*, which quantifies the incidence of symptoms and their frequency (and also provides a quick measure of patient improvement, if it is re-administered at regular intervals).

Interactions and adverse reactions. Today's history-taking process is complicated by the fact that many people use multiple OTC and prescription drugs, as well as nutraceuticals of various kinds. We now know that this situation creates increased risks of intolerance and/or adverse reactions for a variety of reasons. As part of normal history taking, therefore, all herbal, pharmaceutical, and nutritional supplements should be listed in the patient's chart, updated regularly, and reviewed for possible interactions. Clinicians should be cognizant of the fact that there are now commercially available drug-drug interaction software programs, as

Table 34.1 Components of a Comprehensive History

Chief Complaint: The current concern or problem
Present Illness: The timeline and symptoms involved with the current problem(s) and associated complaint(s); functional medicine practitioners add questions that explore any noteworthy *antecedents, triggers and mediators* of the present illness.

Past Medical and Surgical History
 Review of Lifestyle and Habits
 Review of Organ Systems

Considered within the context of underlying mechanisms in the areas of the functional medicine matrix:

Environmental Inputs	Structural
Oxidative Stress	Neuroendocrine
Mind/Body	Detoxification
Immune/Inflammation	GI Function
- Medical problems
 - Surgeries and hospitalizations
 - Traumas
 - Medications
 - Supplements, herbs, nutrients, homeopathics, adaptogens
 - Allergies, sensitivities, or intolerance to medications, herbs, foods
 - Exercise patterns
 - Diet or special dietary habits:
 - What foods are regularly eaten or avoided?
 - Artificial sweeteners or fats: aspartame, sucralose, olestra
 - Social, occupational, and lifestyle history:
 - Relationships (family, work, community)
 - Passions, hobbies, interests
 - Work and potential environmental exposures
 - Habits and addictions: tobacco, alcohol, caffeine, illegal drugs
 - Sexually active (if yes, practicing safe sex?)
 - Spirituality and faith
 - Preventive medicine interventions
 - Vaccinations and immunizations
 - Family history
 - Genetically-linked illnesses and predispositions
 - Family behaviors or emotional tones
 - Lifestyle issues of family members

Differential Diagnosis

well as drug-nutrient, nutrient-nutrient, and botanical-drug publications and programs to help in evaluating the patient's list for potential problems. An article published in 2001¹⁴ identified 27 drugs frequently cited in adverse drug reaction studies. Among these drugs, 59%

Section VII

Putting It All Together

are metabolized by at least one enzyme with a variant allele known to cause poor metabolism. These findings are summarized in Table 34.2.

Table 34.2 Commonly Identified Drugs in Adverse Drug Reactions

Therapeutic Category and Drug Class	Specific Drug
Cardiovascular - Beta blockers - Angiotensin converting enzyme (ACE) inhibitors - Diuretics - Calcium channel blockers - Inotropic agents/pressors	atenolol, metoprolol lisinopril furosemide, hydrochlorothiazide diltiazem, verapamil digoxin
Analgesics - NSAIDs - COX-2 inhibitors	aspirin, piroxicam, ibuprofen, naproxen Vioxx®, Bextra®, Celebrex®
Psychiatric - Tricyclic antidepressants - SSRIs	imipramine, nortriptyline fluoxetine
Antibiotics - Penicillin - Antitubercular agents - Macrolides	amoxicillin isoniazid, rifampin erythromycin
Other - Anticoagulants - Corticosteroids - Anticonvulsants - Antidiabetic agents - Bronchodilators - Electrolytes - Antiemetics or antihistamines	warfarin sodium prednisone carbamazepine, phenytoin insulin theophylline potassium meclizine hydrochloride

Adapted from Phillips KA, et al. Potential role of pharmacogenomics in reducing adverse drug reactions; a systemic review. JAMA. 2001;286:2270-79.

- Other important factors to consider:
- Many pharmaceuticals and herbs pass through the main cytochrome P450 enzymes as substrates, and can act as inducers or inhibitors of these enzyme systems.
 - In addition, the list of enzyme polymorphisms that affect the efficacy and clearance of various drugs and herbs is now extensive and is updated regularly.
 - The prevalence of poor metabolizers (a function of polymorphisms in the P450 system) varies by race. A few examples will bring this point home:
 - Among Caucasians, 12% are poor metabolizers of CYP1A2 substrates, up to 6% of CYP2C9 and CYP2D19, and up to 10% of CYP2D6 substrates.
 - Among Chinese, up to 17% are poor metabolizers of CYP2C19 substrates, and <2% are poor metabolizers of CYP2D6 substrates.
 - In people with Japanese heritage, up to 23% are poor metabolizers of CYP2C19 and <2% are poor metabolizers of CYP2D6 substrates.
 - There are many genetic variants within each group of cytochrome alleles and each has its own incidence among races. For example within the CYP2D6 enzyme, there are at least 31 allele variants, with race data showing presence of allele variants in up to 50% of Chinese, 34% of African Americans, 60% of Japanese, 19% of Koreans, 50% of other Asians, and 34% of Africans. (More information on genetic variability and polymorphisms in detoxification can be found in Chapters 22 and 31.)

Genetic inheritance, diet, and combinations of drugs (and other substances) ingested are all factors in the incidence of adverse drug reactions.¹⁵ A study published in 2003 reported that “one quarter of outpatients had adverse drug events during a three-month period ...”¹⁶ Thirty-nine percent of the ADRs reported were classified as “ameliorable or preventable,” which implies that 61% were not (given current knowledge). The most common cytochrome polymorphisms are listed in Table 34.3, and the Appendix provides an extensive listing of inhibitors and inducers of some important P450s. Clinicians do need to consider ways in which the patient’s history can be evaluated for some of the most common potential problems elucidated by this complex and rapidly growing research.

Table 34.3 Drugs Implicated in Adverse Drug Reactions Metabolized by Enzymes with Variant Alleles Associated with Poor Metabolism

Enzyme	Drugs
CYP1A2	Carbamazepine, diltiazem, erythromycin, fluoxetine, imipramine, isoniazid, naproxen, nortriptyline, phenytoin, rifampin, theophylline, verapamil.
CYP2C9	Fluoxetine, ibuprofen, imipramine, isoniazid, naproxen, phenytoin, piroxicam, rifampin, verapamil, warfarin
CYP2C19	Fluoxetine, imipramine, isoniazid, nortriptyline, phenytoin, rifampin, warfarin
CYP2D6	Diltiazem, fluoxetine, imipramine, metoprolol, nortriptyline, theophylline.

Understanding the Functional Medicine Model: Comprehensive Care, Part II

The review of underlying mechanisms of disease (the functional medicine matrix) is where the functional medicine approach begins to significantly depart from the standard model of care, to establish a more comprehensive model. This section of the comprehensive history is best filtered through the *functional medicine matrix*, a tool that helps organize information, clarifying the level of present understanding and illuminating the need for broader investigation (an example of “knowledge-coupling” as proposed by Dr. Larry Weed^{17,18}). Let's look at this methodology, as illustrated by a continuation of the “Broken Toe” case (see Figure 34.3).

The functional medicine matrix tool was developed by the Institute of Functional Medicine's Curriculum Committee through a two-year process of repeatedly asking the question: “For comprehensive evaluation of underlying elements and mechanisms of disease, what categories would need to be represented?” This question was subjected to all areas of scientific inquiry in the area of human biology including the expanding research in the importance of mind-body-spirit web-like interconnectedness with physiology. All areas of credentialed

medical practice were also drawn into this web of inquiry. We have entered the 21st century with the real possibility of moving medical care from a focus on the differential diagnosis to a focus on understanding the mechanisms associated with the origins of the signs and symptoms that underlie the patient's dysfunction. In 21st century medicine, we will learn to extract the explanation from our understanding of specific antecedents, triggers, and mediators, as well as the frequency, intensity, and duration of the patient's symptoms.¹⁹

The Institute for Functional Medicine teaches the expanded use of the evolving functional medicine matrix in the six-day course, *Applying Functional Medicine in Clinical Practice* (AFMCP). Information about that course can be reviewed on IFM's web page: www.functionalmedicine.org. The first step in the utilization of the matrix requires a disciplined understanding and review of each element of the matrix, connecting important signs and symptoms to their appropriate element or mechanism of action. The short-hand version of this step in the use of the matrix is illustrated in Figure 34.3 for our sample case (we return here to the older version of the matrix). The web-like connections within the eight elements of the matrix will be further elaborated as we progress through this illustrative case study.

The Comprehensive Physical Exam

The physical exam is a key component of patient assessment in nearly all healthcare disciplines. Common components of the basic physical exam are listed in Table 34.4. More extensive systemic exams can be completed, depending on initial findings, specific symptoms, or specialty focus. Signs of undernutrition or altered nutrition are summarized in the Appendix and are extremely important to watch for. For example, many patients with bulimia, and between 24–76% of patients with anorexia nervosa,²⁰ have dermatologic and physical exam findings of multiple nutritional deficiencies; knowing what those are can help identify a serious underlying problem. Nutritional deficiencies are also common in the elderly, who have a significant risk of being deficient in at least two nutritional cofactors.²¹

Figure 34.3 The matrix as applied to the “Broken Toe” case

Comprehensive history taking and physical exam from a functional medicine perspective require a different time frame and the use of additional data-gathering and sorting tools. It is impossible to investigate the patient's unique health history using a review of mechanisms, *and* perform a thorough physical, within the time constraints of a brief office visit. Recent research has documented that all primary care providers in the present healthcare environment face a significant time problem in managing patients with chronic, complex illnesses.²² However, after the comprehensive assessment is completed, it is then possible to break further assessments and interventions into shorter segments; but a comprehensive approach to the first visit is critical.

Sidney Baker, MD tells a story about his early medical training and mentoring while serving in Kathmandu, Nepal in 1959. His senior medical tutor, before the completion of a patient workup, always asked: “Sidney, is there anything else we can do for this patient?” We suggest a similar question: “What additional information would be helpful to understand this patient?” Chapter 35 focuses on just that question, emphasizing dietary assessment and the benefits and limitations of laboratory assessment.

Table 34.4 Common Components of the Basic Physical Exam

General	Height, weight, blood pressure, pulse, respiratory rate, temperature, appearance, somatotype, emotional state
Head	Configuration, shape, symmetry or asymmetry, excess hair or hair loss, lesions, scars, bruits or tenderness behind the ears, tenderness on the temporal arteries, prominence of vessels
Eyes	Visual acuity, conjunctiva, sclera color, extraocular movements, visual fields by confrontation, papillary reaction to light and accommodation, iris, funduscopic examination of the lens, disks, retinal vessels, upper and lower lids
Ears	Auditory acuity, shape, external auditory canal, tympanic membranes and acoustic meatus, hearing—bone/air conduction
Nose	Air movement, nares, turbinates, polyps, septum, mucosa, drainage, rhinorrhea, smell
Mouth	Symmetry, control of lips and jaw. Oral exam: lips, mucosa, gingival plaque; normal, decayed, or missing teeth; enamel staining/color, dentures, or implants; degree of amalgams and what type, occlusion; saliva, ducts, tongue color, fissuring, tastebud lack or prominence, tonsils, pharynx, redundancy of tissue, uvula at rest and during phonation, lesions, infections
Neck	Symmetry and configuration, movement, strength; mobile and midline trachea; cervical anterior, posterior, and supraclavicular lymph nodes; thyroid, bruits, carotid pulses, muscle symmetry, masses, cysts. Suprasternal notch or supraclavicular fossa fullness. Inspect and palpate spine.
Axilla	Nodes, masses, hair presence or absence
Chest	Symmetry, excursion/movement. Palpate for tenderness of ribs, masses, maldevelopment, or crepitus.
Breasts	Symmetric, masses, cysts, tenderness, discharge, lesions on nipple
Lungs	Rate and rhythm of respiratory cycle, vital capacity, hoarseness, clarity with breathing, symmetric, rhonchi, rales, wheezes, crepitus, pleural rub, percussion symmetry
Heart	Rhythm; heart valves—sounds, murmurs, changes with position; pulses—radial, femoral, popliteal, dorsalis pedis, lateralization of the point of maximal impulse; extra sounds—rubs, clicks
Abdomen	Symmetry; liver or spleen enlargement; bowel sounds, bruits, friction rubs, tenderness, masses; percussion tenderness; rectus diastasis, hernias. Palpate the femoral and iliac arteries, abdominal aorta. Palpate lymph nodes of the inguinal canal
Back	Symmetry of station, musculature, posture. Vertebral tenderness. Range of motion of neck, thorax, lumbar spine
Musculoskeletal	Trigger-point tenderness; normal movement of the shoulders, elbows, wrists, hands, hips, knees, ankles, toes—opening/closing of hands; hips, knees, ankles, toes. Swelling, tenderness, or asymmetry of joints or tendons; signs of ligament laxity; signs of previous or current injury.
Rectal	Perianal or anal lesions, fissures, masses; sphincter tone; prostate size (males), retroflexed uterus (female)
Genitourinary	Male: scrotum, testes, epididymi, penis, glans, lesions Female: external genitalia, introitus, mucosa of the introitus, vagina, cervix; presence of rectocele/cystocele; palpation of the cervix, uterus, and adnexa; discharge or masses; ovaries present
Skin	Texture, lesions, abnormal discolorations, hair pattern; subcutaneous fat texture. Nails—dysmorphic, texture or asymmetry, marks, abnormal thickness or consistency. Nail beds—color, lesions
Neurologic	Auditory acuity, intelligence, memory, mood, speech, gait, balance, involuntary movements. Cranial nerves 1–12; cerebellar exam; frontal release signs. Deep tendon reflexes of the biceps, triceps, brachioradialis, patellar, Achilles, and plantar. Proprioception, vibratory sense; orientation, mini-mental status. Can the patient get up from sitting, walk across the room, pick up a piece of paper, walk back, and sit down?

The matrix, however, is extremely useful in identifying where the preponderance of evidence from the initial history and physical lies, and also in clarifying where further investigation (e.g., laboratory work) is needed. For example, indicators of *inflammation* on the matrix might lead the clinician to request tests for specific inflammatory markers (such as hsCRP, interleukin levels, and/or homocysteine) to help illuminate the “immune/inflammatory” processes that might be at work. Essential fatty acid levels, methylation pathway abnormalities, and organic acid metabolites help determine adequacy of *dietary and nutrient* intakes. Markers of *detoxification* (glucuronidation and sulfation, cytochrome P450 enzyme heterogeneity) can determine functional capacity for molecular biotransformation. Neurotransmitters and their metabolites (vanilmandelate, homovanillate, 5-hydroxyindoleacetate, quinolininate) and hormone cascades (gonadal and adrenal) have obvious utility in exploring “messenger molecule” balance. CT scans, MRIs, or plain x-rays extend our view of the patient’s *structural* dysfunctions. The use of bone scans, dexta scans, or bone resorption markers^{23,24} can be useful in further exploring the web-like interactions of the matrix. Newer, useful technologies such as functional MRIs, SPECT or PET scans open a frontier of more comprehensive assessment of metabolic function within organ systems. But it is the process of completing a comprehensive history and physical and then charting these findings on the matrix that best directs the choice of laboratory work and successful treatment.

Five Levels of Functionality: Selecting Effective Treatments

Distilling the data from the history, physical exam, and laboratory into a narrative story line that includes antecedents, triggers, and mediators can be daunting. Key to developing a thorough narrative is viewing the story through the lens of the functional medicine matrix, which facilitates organizing the story according to a set of eight common underlying mechanisms of (or influences upon) health. However, even with the matrix as an aid to synthesizing and prioritizing information, it can be very useful to consider the impact of each variable at five different levels:

1. Whole body (the “macro” level)
2. Organ system
3. Metabolic or cellular

4. Subcellular/mitochondrial
5. Subcellular/gene expression

Therapies should be chosen for their potential impact on the most central imbalances of the particular patient; evaluating interventions that are available at each of the five levels can help to identify a reasonably comprehensive set of options from which to choose. The following lists incorporate only a few examples of various types of interventions within these five different levels. The rest of this book contains many more.

1. **Whole body interventions:** Because the human organism is a complex adaptive system, with countless points of access, interventions at one level will affect points of activity in other areas as well. For example, improving the patient’s sleep will beneficially influence the immune response, melatonin levels, T cell lymphocyte levels, and will help to decrease oxidative stress. Incorporating exercise markedly affects many areas of the matrix; we know that exercise reduces stress, improves insulin sensitivity, and improves detoxification, just to mention a few instances. Reducing stress (and/or improving stress management) can reduce cortisol levels, improve sleep, improve emotional well being, reduce the risk of heart disease, and so forth. Changing the diet can have myriad effects on health, from reducing inflammation to reversing coronary artery disease. (See Chapter 26 for a discussion of the many potential benefits of dietary interventions.)
2. **Organ system interventions:** These interventions are used more frequently in the acute presentation of illness. Examples include splinting; draining lesions; repairing lacerations; reducing fractures, pneumothoraxes, hernias or obstructions; or removing a stone to reestablish whole organ function. There are many interventions that improve function. For example, bronchodilators improve air exchange, thereby decreasing hypoxia, reducing oxidative stress, and improving metabolic function and oxygenation in a patient with reactive airway disease.
3. **Metabolic or cellular interventions:** Cellular health can be addressed by insuring the adequacy of macronutrients and micronutrients, the cofactors for intracellular metabolism. For example, deficiencies of folate, vitamins B6, and B12 are

widespread.²⁵ An individual's metabolic enzyme polymorphisms can profoundly affect his or her nutrient requirements. Providing adequate essential amino acids, vitamins, and cofactor minerals in the diet according to the patient's unique metabolic needs is essential. The frequency and impact of the greater than 50 identified enzymatic polymorphisms that are common in the population have been outlined.²⁶ These affect enzymatic systems in the cytosol and mitochondria. There are many more examples of appropriate nutrient interventions that should be made in the context of the patient's condition. For example, adding conjugated linoleic acid (CLA) to the diet can alter the PPAR system, affect body weight, and modulate the inflammatory response.^{27,28,29} However, in a person who is diabetic or insulin resistant, adding CLA may induce hyperproinsulinemia, which is detrimental.^{30,31} Altering the types and proportions of carbohydrates in the diet may increase insulin sensitivity, reduce insulin secretion, and fundamentally alter metabolism in the insulin-resistant patient. Alcohol consumption and smoking both change requirements for many of the nutrient and vitamin cofactors. Decreasing use of these substances may lower excessive demand and exert less pressure on the cellular detoxification pathways in the lungs and liver. Supporting liver detoxification pathways with supplemental glycine and N-acetylcysteine improves the endogenous production of adequate glutathione, an essential antioxidant in the central nervous system and GI tract. N-acetylcysteine also plays a role in the sulfur conjugation pathway that is important in the detoxification of acetaminophen and other substances.

4. **Subcellular/mitochondrial interventions:** There are many examples of mitochondrial nutrient-support interventions.^{32,33} Inadequate iron intake causes oxidants to leak from mitochondria, damaging mitochondrial function and mitochondrial DNA. Making sure there is sufficient iron helps alleviate this problem. Inadequate zinc intake (found in >10% of the U.S. population) causes oxidation and DNA damage in human cells.³⁴ Insuring the adequacy of antioxidants and cofactors for the at-risk individual must be considered in each part of the matrix. Carnitine, for example, is required as a carrier for the transport of fatty

acids from the cytosol into the mitochondria, improving the efficiency of beta oxidation of fatty acids and resultant ATP production. In patients who have lost significant weight, carnitine undernutrition can result in fatty acids undergoing omega oxidation, a far less efficient form of metabolism.³⁵ Patients with low carnitine may also respond to riboflavin supplementation.³⁶

5. **Subcellular/gene expression interventions:** As will be clear to the reader of this book, many compounds interact at the gene level to alter cellular response, thereby affecting health and healing. Any intervention that alters NFκB entering the nucleus, binding to DNA, and activating genes that encode inflammatory modulators such as IL-6 (and thus CRP), cyclooxygenase 2, IL-1, lipoxygenase, inducible nitric oxide synthase, TNF-α, or a number of adhesion molecules will impact many disease conditions.^{37,38} There are many ways to alter the environmental triggers for NFκB, including lowering oxidative stress, altering emotional stress, and consuming adequate phytonutrients, antioxidants, alpha-lipoic acid, EPA, DHA, and GLA.³⁹ Adequate vitamin A allows the appropriate interaction of vitamin A-retinoic acid with over 370 genes.⁴⁰ Vitamin D in its most active form intercalates with a retinol protein and the DNA exon and modulates many aspects of metabolism including cell division in both healthy and cancerous breast, colon, prostate, and skin tissue.⁴¹ Vitamin D has key roles in controlling inflammation, calcium homeostasis, bone metabolism, cardiovascular and endocrine physiology, and healing.⁴² Many of the finer points of the functions of vitamins A and D in health have been covered earlier in the text. Folate and B12 are key in DNA repair. Requirements vary among different patients; therefore, adequacy must be individually determined and maintained.⁴³

Understanding the Functional Medicine Model: Comprehensive Care, Part III

Returning once again to the "Broken Toe" case, we must now connect the Part I data on antecedents, triggers, and mediators with the Part II assessment of underlying mechanisms to answer the key clinical question: At what levels can we intervene effectively? By this time, most of the issues mentioned below will likely

have been resolved and the remaining questions will be answerable, leading to clear indications for treatment.

1. **Whole body interventions:** Depending on our findings, we may determine that the patient needs to use a balance aid, or learn some core strengthening exercises to avoid further injury. Checking for balance on a neurologic exam can be essential to configuring an appropriate secondary prevention program. If osteoporosis is a factor, dietary and exercise recommendations may be a high priority.
2. **Organ system interventions:** Splinting or immobilization by buddy taping or wearing a stiff-soled shoe reduces fracture line movement and speeds healing. Orthopedic consultation for possible pinning may be in order, depending on the fracture site and extent (i.e., great toe, middle phalanx involving the joint space). Checking for drug/nutrient interactions may uncover causes of calcium or magnesium deficiency (environmental input/diet element of the matrix). Consider determining bone density; perhaps she has significant osteoporosis. Suggest dietary changes to improve calcification and healing, timing of fiber, and calcium or magnesium supplementation. If she is on calcium, evaluate her source. Is she on a proton pump inhibitor or acid blocker that may be affecting B12 availability and absorption? Has she had prior injury and has there been a program of reconditioning? Consider gonadal function and bone strength. How is her eyesight, as well as her proprioception or vibratory sense?
3. **Cellular/metabolic interventions:** Does the patient live north of 35 degrees N, or south of 35 degrees S? What is the color of her skin? Does she get enough UV B light? Is she inside all the time? Is she always covered with clothing or sunscreen? In other words, is she at risk for vitamin D deficiency and thus secondary hyperparathyroidism, resulting in osteomalacia or osteoporosis? What is her caffeine consumption? Caffeine increases calcium and magnesium loss in the urine. Are there gut absorption problems that could affect calcium absorption? Is she taking a diuretic? Does she have indices of inflammation? TNF- α inhibitors have been associated with slowing the speed of fracture healing. Is she taking an anti-inflammatory? Anti-inflammatories can also slow the healing of fractures.⁴⁴

4. **Subcellular/mitochondrial interventions:** Are there any obvious mitochondrial issues? Is nutrient intake adequate? Is she on a level of fixed income that is associated with poor nutrient status? Does she have adequate energy? Excessive fatigue can interfere with compliance on treatment recommendations such as exercise or physical therapy.
5. **Subcellular/gene expression interventions:** Does she have any physical exam findings or genetic history that would suggest she has an altered requirement for specific nutrients? Is she getting enough vitamin A, vitamin K, vitamin D? Does she need intervention to alter NFKB with phytonutrients, or nutritional?^{45,46}

Re-Assessment: After appraising the five levels discussed above, and assessing and initiating appropriate interventions, one last re-assessment question should be asked: What is now known with certainty, and which points on the matrix still merit further investigation? A final review of the matrix, this hologram that you have constructed, can elucidate areas that still need fleshing out, or that may not truly reflect the patient's reality. Allow yourself a frank and critical review process.

Consider referrals: No single practitioner—and no single discipline—can cover all the viable therapeutic options. Interventions will differ by training, licensure, specialty focus, and even by beliefs and ethnic heritage. However, all the specialties and disciplines can—to the degree allowed by their training and licensure—use a functional medicine approach, including integrating the matrix as a basic template for organizing and coupling knowledge and data. So, where possible, seek out other providers who have also acquired some functional medicine training. Treatment success can be affected by the cultural bias of the patient and the provider, so get to know your colleagues in other fields.

Educate yourself about what other disciplines have to offer. Should any medical specialists be involved? If you are not well trained in physical medicine, consider a chiropractor or osteopathic physician. If your experience with botanicals, supplements, and dietary interventions is limited, a naturopathic physician might be a wise choice. In-depth nutritional counseling is offered by nutritionists and registered dietitians. Acupuncture has much to offer, as does Traditional Chinese Medicine (TCM). It is beyond the mission of this book to discuss the training, scope of practice, or therapeutics of the

many different healthcare approaches available today, but many publications and websites do provide such information. Regardless of what discipline you have been trained in, developing a network of capable, collaborative clinicians with whom you can co-manage challenging patients and to whom you can refer for therapies outside your own expertise will enrich the care your patients receive, and will strengthen the clinician-patient relationship. Many patients do not tell one practitioner about care they are receiving from other practitioners. Keep those lines of communication open and alive. All referral relationships should be handled with the same professionalism and courtesy.

A Concluding Short Story of Comprehensive Care

We'll let another case demonstrate the value to the patient of using a comprehensive functional medical model of care. The *Lancet* reported a case study in March 1999 in a paper titled: "A Woman Who Left Her Wheelchair."⁴⁷ A 32-year old woman had suffered for over two years with progressive muscular weakness and pain. Her standard (and very thorough) medical workup had ruled out emergency spinal crisis with appropriate imaging techniques including CT scan, MRI, and bone scan. Her neurological exam did not show sensory or motor disturbance, or muscle atrophy. Electromyography and nerve conduction studies were reported to be normal. A diagnosis eluded her physicians, except for a documented iron-deficiency anemia that was treated with iron-dextran, given intravenously. Her weakness progressed over the ensuing two years, eventually requiring use of a wheelchair.

In 1997, after two years of investigation, a new review of the present medical problem, filtered through the lens of *antecedents/triggers/mediators*, revealed a long-term history of Crohn's disease, requiring steroids by age 21, followed more recently by a small-bowel resection. She had *not* experienced the symptoms of progressive muscular weakness and pain prior to the small-bowel resection. In a *review of underlying mechanisms of illness*, the question of nutrient adequacy in the context of chronic Crohn's and small-bowel disease was raised. With small-bowel resection of one meter of ileum, bile salt loss with steatorrhea can occur; she did suffer from foul-smelling stools. A fecal sample from the patient showed 90 g of fat loss over 24 hours. A complete meta-

bolic panel was unremarkable except for elevated values of alkaline phosphatase and markers of bone reabsorption (osteocalcin and pyridinoline cross-linked telopeptide), but with normal calcium and parathyroid hormone. Further testing demonstrated a 25-OH-Vit D level that was profoundly low (2.4 ng/mL).

Tying together the antecedent conditions, triggers, and mediators of her illness with the review of underlying mechanisms of illness, a diagnosis was made: hypovitaminosis D due to selective fat malabsorption (including fat-soluble vitamin D) after small-bowel resection for resistant Crohn's disease. A treatment plan was instigated. Her metabolic stores were repleted using parenterally administered 1,25 dihydroxyvitamin D3 with additional calcium, and a phosphate-rich diet, low in fat (meat, fish, liver and root vegetables). Within three weeks she was able to walk without assistance; her weakness and bone pain resolved and did not return.

Assessment and Therapeutic Strategy—A Place to Start

- ▶ *Elimination Diet and Laboratory Testing*
- ▶ *Identifying Practical Interventions that Help to Normalize Multiple Symptoms*

Elimination Diet and Laboratory Testing

Dan Lukaczer, ND, and Barb Schiltz, MS, RN

Introduction

“Where do I start?”

“What’s the best nutritional intervention?”

“Which lab test should I order?”

These three questions are the most frequently asked by clinicians new to functional medicine. As even a quick review of the preceding chapters will attest, there is often no simple (or single) diagnosis or treatment for patients with chronic health issues. This is the bane and the boon of functional medicine. Real people, real lives, and real problems frequently don’t fit neatly into simple diagnostic (or treatment) categories. There is a complexity to medicine when viewed in this way that makes it forever fascinating, challenging and new, but also frustrating because of the myriad threads that must be woven together into a coherent pattern.

When viewed through the functional medicine lens, the conventional medical model often does not approach the patient holistically, and it stops short of approaching disease from the perspective of underlying mechanisms. The functional medicine model encompasses biochemical individuality in the context of multiple mechanisms and environmental influences; the symphony (some would say cacophony) of signs and symptoms must be organized in a way that suggests a discernable pattern. The preceding chapters have provided many insights on how to approach patients from this perspective, but questions about getting down to specific actions on Monday morning may still exist.

That larger vision, the bird’s eye view, must be translated into pragmatic steps that any practitioner interested in this medicine can take.

Although the practice of functional medicine can be frustratingly complex when piecing together the puzzle that each new patient presents, there are, in fact, specific approaches that help make the complexity manageable. One of those—the use of the functional medicine matrix—was presented in the preceding chapter and can help to define where on the interconnected web the clinician can begin. This chapter will focus on helpful first steps and approaches that can be used to set the groundwork for more detailed evaluation and treatment to be performed subsequently. The three major topics we will cover are dietary assessment, understanding laboratory assessment, and utilizing practical interventions that work to normalize multiple systems (more “bang for the buck”).

The First Step: Dietary Assessment

While the possible interventions in functional medicine are numerous, the place to start is almost invariably with food. Too often we are so enamored of the newest test or diagnostic procedure that we forget the fundamental step of assessing dietary intake. Everyone must eat. Dietary assessment can provide significant clues about the patient’s problems. It has been estimated that over the course of 70–80 years of living a person consumes approximately 80–90,000 individual

meals. Thousands of compounds must be inspected, recognized, broken down, packaged up, and digested or discarded. Given the enormity of this process, and the many opportunities for things to go amiss, it clearly makes sense to begin our evaluation here.

How does a clinician assess this most basic question: Is the patient eating (or not eating) in a way that has become either the cause of, or a mediating influence on, his or her presenting signs and symptoms? From a scientific perspective, the answer is often difficult to pin down. The underlying mechanisms that elicit a food reaction are complex and even controversial.¹ Food reactions can run the gamut from

- those that are immunologically mediated (immediate or delayed allergic or hypersensitivity reactions, respectively), to
- non-immunologically mediated reactions such as food intolerances or sensitivities (e.g., lactose intolerance, sulfite or salicylate sensitivity), to
- reactions secondary to the effects of certain foods on other regulatory systems (e.g., simple sugars and reactive hypoglycemia), to
- reactions associated with the effects of a specific food on bowel flora (described by Hunter as “enterometabolic” reactions¹).

A variety of assessment techniques and tools have been used to identify these food-related reactions. Unfortunately, *none* are foolproof. Generally, the most cost-effective and accurate method of identifying reactivity to specific foods is an oligoantigenic diet followed by reintroduction or food challenge. (This is not to deny the utility of laboratory testing, which can play a very important role in patient assessment; right now, however, we are focusing on an almost universally useful and affordable approach—dietary assessment.)

Why is assessment of food reactions so important? Even a quick scan of the medical literature clarifies the connection between food and disease (see Chapter 26 for a comprehensive review of the subject). Studies have been conducted on dietary interventions in the treatment of, for example, rheumatoid arthritis,² irritable bowel syndrome,³ migraine headaches,⁴ attention deficit disorder,⁵ infantile colic,⁶ otitis media,⁷ atopic dermatitis,⁸ chronic urticaria,⁹ and Crohn’s disease.¹⁰ All

have shown a connection with food as an etiological agent, to one degree or another. While clearly not all patients in these or other conditions respond positively to a dietary approach, dietary changes can produce a sustained positive response in a subset of patients with chronic complex problems. Therefore, this is an extremely important starting point.

What is needed to carry out such a protocol? First, patients must be educated to understand that this approach can provide information essential to understanding their problems. Second, patients need to know that the approach is valid, is “do-able,” and can be accomplished within a limited time frame. Third, the clinician needs tools to easily and comprehensively test the hypothesis that diet is an influence on the patient’s health.

Assessment of Food Reactions with an Elimination Diet

Diet Diary

The first step is to find out what the patient is eating regularly. This can be accomplished with the use of a three-day diet diary. A sample form is provided in the Appendix. A careful review of the diet diary will often identify foods that are eaten frequently and extensively, and therefore may be the first target for an elimination diet. However, given that food reactions often present with delayed onset of 4 to 72 hours, food diaries are not always able to clarify which particular food(s) may be the offending agent(s). The idea that one single food is culpable, while enticing, is an approach that does not generally hold up in clinical practice.

The Program

A program that eliminates certain foods or food groups from the diet for diagnostic purposes can take many forms. Simpler programs may eliminate only one or two specific foods or food groups, often focusing on specific proteins found in dairy, wheat (or all gluten-containing foods), egg, soy, pork, beef, or corn. These more narrowly focused dietary exclusion programs can be particularly useful when treating children, because they are easier to carry out than a program that eliminates many foods and food groups.

A comprehensive program that eliminates more foods may be advisable as a starting point for many

¹There are many chapters in this book where various approaches to assessing food reactions are discussed. Please see the Index for help in locating specific content.

adult patients. A sample comprehensive elimination diet can be found in the Appendix, with a list of foods to exclude, foods to include, and a chart for recording reactions upon reintroduction. This example eliminates most foods that have been found, over time and across many patients, to produce reactions. Such a program is easily modifiable to fit individual patients and situations; it allows the practitioner to throw a broader net that is more likely to catch the right fish. The common foods eliminated in this program include gluten, dairy, beef, pork, citrus fruits, corn, eggs, soy, various food additives, and colorants. Many clinicians have used this or a similar program and have found it to be generally well tolerated.

There is really no typical or normal response. Often, a patient's primary health concerns improve significantly within the first three weeks on such a program. Additionally, patients often report other nonspecific improvements such as increased energy, mental alertness, a general sense of improved well-being, or the disappearance of symptoms they have lived with for years. It is prudent to warn patients that they may have some initial reactions to the program, especially in the first week or ten days. Such reactions are sometimes difficult to explain. They may be secondary to the so-called Herxheimer reaction,¹¹ to alterations in GI function from diet-induced changes in flora, to caffeine or simple sugar withdrawal, or to other less well understood causes. Symptoms may include changes in sleep patterns, lightheadedness, headaches, joint or muscle stiffness, constipation, diarrhea, rash or pruritis. Generally, such symptoms abate in the first 7–10 days of the program and can be handled with supportive measures, including activated charcoal, Alka Seltzer Gold®, additional fiber, rest, and saunas.

While changing food habits dramatically can be a complex, difficult, and sometimes confusing process, given the proper tools, encouragement, and a circumscribed timeframe, it can be a very practical and empow-

ering endeavor. Along with providing inspiration and clear dietary instructions, the clinician should supply patients with written information tailored to their specific program. These include an explanation of the process, general food guidelines (what to eat, what not to eat), shopping lists, and sources of hidden foods. The Appendix provides an example of some patient handouts that can be adapted for these purposes.

An elimination diet should be carried out under close supervision for an initial period of not less than three weeks. While the program is generally not calorie restricted, many patients do lose 4–6 pounds over this time. At the three-week mark, it is reasonable to proceed with a careful reintroduction of excluded foods and an evaluation of the response. However, the program can be continued uninterrupted for as long as the clinician deems necessary (and the patient is compliant). A patient who has experienced noticeable improvement in certain symptoms, and is interested in continuing without reintroducing foods that have been excluded, should be strongly encouraged. In fact, in some conditions the full extent of improvement may not be completely realized for months.¹¹ There are no dietary deficiencies that we are aware of that make a long-term commitment to this program contraindicated.

Reintroduction Process

When excluded foods are reintroduced, the patient should use a systematic recording method, the main features of which should be:

- A particular excluded food is chosen for reintroduction. (Often those foods that were most commonly eaten prior to the elimination diet are chosen first.)
- The food is ingested two to three times over the course of a day.
- The patient otherwise continues to eat only the foods on the current food list.
- Responses are recorded on a chart such as the one shown in the Appendix. (The patient may use different headings to correspond with whatever signs and symptoms are experienced.)
- Only one new food is introduced at a time.
- The patient waits at least two days (48 hours) before challenging a new food.
- If a reaction is noted, the patient waits until that reaction has dissipated before reintroducing another food. (If the patient is unsure whether a reaction occurred, the same food is retested in the

¹¹ The Jarisch-Herxheimer reaction (often referred to as Herxheimer or Herx) is believed to be caused by gut organisms dying off at a rapid rate. Many of these organisms, or their metabolic by-products, may be absorbed into the systemic circulation as endotoxins and overwhelm the liver's ability to adequately scavenge and process. Systemic reactions can thus occur and may include joint pain, fever and malaise. These reactions were originally observed in patients with syphilis who received mercury treatment, but have also been more recently characterized in Lyme disease treatment as well. Some clinicians also refer to this phenomenon as a "detoxification" or "clearing" reaction.

same manner after the possible reaction has dissipated.)

- A reactive food is recorded and kept on the excluded list.

Many underlying mechanisms may cause reactions to a given food or food group. Genetic predisposition, impaired enzyme or acid secretion, protozoal infection, bacterial dysbiosis, medications, concurrent disease, nutritional insufficiency, and aging all can play a role. Addressing these underlying issues may eventually allow the patient to resume eating some foods to which they had previously reacted. Even fairly reactive foods may eventually be tolerated in small amounts on an occasional basis.

Evaluating the Role of Laboratory Testing in Functional Medicine

Laboratory evaluation can play a pivotal and central role in clinical practice. Among its many uses are: identification of the underlying etiology of a health condition, serving as an aid to accurate diagnosis, providing a predictive measure of future health problems, or tracking the progress a patient makes on a particular intervention. The question of what laboratory tests are useful from a functional medicine perspective seems to take on a larger and even more complicated role than in the conventional realm. In the functional medicine work-up, the clinician often looks to lab, not only for signs of pathological change, but also to assess more subtle signs of imbalance or dysfunction. Bacterial dysbiosis that may be associated with digestive or systemic complaints, functional folic acid deficiency that may be associated with a mood disorder, or estrogen/progesterone shifts that may be associated with fatigue or sleep disturbances are not completely diagnosable by laboratory measures. In fact, these laboratory evaluations, if taken outside the context of the patient's totality of signs and symptoms, may not offer significant clues.

For example, two individuals may show a modest elevation in serum homocysteine, a functional test of folic acid insufficiency. In a patient who suffers from depression, this may be a key finding in clarifying the underlying etiology of the depression. In another patient, this functional folic acid deficiency may be unassociated with any sign or symptom. While it may be useful to replete with folic acid regardless, it is a less significant finding and in fact may not be a laboratory

test that one would normally request for an individual with no overt symptomatology. The research literature clearly supports the link between depression and elevated homocysteine.^{12,13} However, it just as clearly shows that not all depressed individuals will have an elevated homocysteine, and not all elevated homocysteine will result in depression. It is the context within which the clinician finds the patient that is important for ordering and then interpreting that laboratory marker.

Bacterial dysbiosis is another diagnosis that should not be made out of context. Clinicians may find that patient stool cultures are often positive for unusual or non-commensal bacteria. In our experience, this finding can occur in both symptomatic and healthy individuals, and it is only within the framework of the total patient work-up that the relative importance of such results is understood. The patient may present with other relevant history such as digestive complaints following repeated courses of antibiotics, unexplained joint pain or fatigue, and dermatological symptoms. When the available information coalesces into a coherent story suggesting gut dysbiosis as an underlying cause, then the laboratory results do help in confirming the patient's problem and planning a therapeutic intervention.

While laboratory evaluation can thus be of significant importance to the functional medicine practitioner, he or she must be careful to scrutinize the utility and predictive value of each laboratory test selected. There are many laboratory tools from which to choose and there is no one lab test that will uncover the dysfunction(s) in all patients. As is always the case in good health care, functional medicine practitioners first perform a careful history and physical exam, including the review of mechanisms (described in Chapter 34), and sorting the information on the functional medicine matrix. Those findings, combined with any laboratory results selected in the initial work-up, will in large part determine where on the matrix to focus initially. For specific laboratory tests to consider in various situations, the practitioner is referred back to other sections of the book, particularly *Fundamental Clinical Imbalances* and *A Practical Clinical Approach*. The scope of this section will be to provide some general information that can be of use in selecting laboratory tests.

In functional medicine, laboratory evaluation is often on the cutting edge of clinical science. It is an area of ongoing and dynamic research that can help us assess functionality in new and exciting ways. However,

a thorough understanding of variability, precision, and accuracy should be foremost in the clinician's mind when considering any new or unfamiliar laboratory assessment. Functional medicine teaches us to understand and assess fundamental physiological processes and to recognize subtle signs and symptoms in an interconnected mosaic. Basic sciences, cell physiology, animal studies, epidemiological, case-controlled, and randomized controlled trials help us arrive at reasonable conclusions and follow up with integrative interventions. When assessments and interventions do not yet have many years of valid and reproducible data behind them, the clinician (in any discipline) must use both art and science to weave together the history, physical exam, and laboratory findings and filter those conclusions through a vast array of scientific data to arrive confidently at a useful place to begin. We are always functioning in an imperfect world with incomplete data. Lab tests may be valuable even if they are not definitive; they can provide general information and clues to potential underlying problems, helping us to decipher the complex tapestry of a patient with chronic unwellness. And, we must use a reliable standard of scrutiny and evaluation in the selection of laboratory tests upon which that patient's health may depend.

Assessing the Performance of a Laboratory Test

To be used with a high degree of confidence in clinical decision making, laboratory methods must meet certain standards of statistical reliability. Simply put, a test must be reproducible over time, with variability that is limited to known parameters and is not so large that it renders interpretation of the findings problematic. That is, one must be able to assume that a change in a test result is a result of the treatment plan, not the result of wide variability in the test itself. The reliability of a test includes what are termed analytical and non-analytical factors.

Analytical factors are broken down into test accuracy, precision, sensitivity, and specificity. These basic concepts, discussed below, are the cornerstones of analytical reliability. If a given test does not have reasonable precision, accuracy, specificity, and sensitivity, it is a test with little reliability.

Measurements of *accuracy* and *precision* reveal a test's basic reliability. Accuracy and precision can be compromised by fluctuations in temperature, variability in volume sample, adequacy of reagent used, changes in

environment, and/or inconsistent handling of specimens. Accuracy and precision are measured and tested through duplicate sampling and internal quality control procedures. A test is *accurate* when it measures what it was intended to measure—the true value of concentration of the substance being measured in a given sample. A test is said to be *precise* when repeated analyses on the same sample give very similar results. When a test method is precise, the amount of random variation is small. A precise test method has results that are reliably reproduced time after time. A test method can be precise (reliably reproducible) without being accurate (measuring what it is supposed to measure), or vice versa.

As a test is performed on patient specimens, its accuracy is routinely monitored with a control specimen. The control has a known test value and is analyzed alongside patient specimens, revealing whether the test measurement process is correct. Although a test that is 100% accurate and 100% precise is the ideal, in reality, tests, instruments, and personnel perform less perfectly than that. A small amount of variability does not usually detract from the test's value. The level of accuracy and precision that can be obtained is specific to each test method. For newer laboratory assessments, these measurements should be requested from the individual laboratory, and if this information is not forthcoming, or is of poor quality or high variability, one should have a healthy degree of skepticism regarding the usefulness of that test (or that laboratory).

While accuracy and precision are critical components of a lab value, a laboratory test must also be able to detect abnormalities with reasonable certainty. How likely is it that an individual has the disease or condition that the test suggests? That question is influenced by both false positives (reporting the patient has the condition when he/she does not) and false negatives (reporting the patient free of the condition when she/he is not). The clinician will want to know the chances of a test delivering either a false negative or a false positive—if those chances are too high either way, using the test may not be advisable.

To this end, labs develop and monitor statistics on each test's diagnostic *specificity* and *sensitivity*. These measurements reveal how likely a false negative or false positive result is when a particular test is performed by a specific lab. *Sensitivity* is the ability of a test to correctly identify individuals who have a given disease or disorder. For example, a certain test, such as an ova and parasite

examination of stool, may have a sensitivity of 90% for diagnosing an infection with the protozoa *Blastocystis hominis*. This would mean that if 100 people known to be infected with the organism are tested by that laboratory facility, the test will correctly identify 90 of those 100 infections. The other 10 people who were tested also have the parasite, but the test will fail to detect it (the test delivers a false negative). A test's sensitivity becomes particularly important when a clinician is seeking to exclude a significant health issue that would change the intervention. In this example, believing that the organism is not present may lead to trying therapies that will not be effective for the real problem. The more sensitive a test is, the fewer false negatives it produces. In summary, a false negative fails to expose a condition that is present; a high rate of false negatives indicates the test has poor sensitivity.

Specificity is the ability of a test to correctly exclude individuals who do not have a given disease or disorder. Using a different example, testing a blood specimen for elevated IgG antibodies to egg might have a specificity of, say, 70%. If 100 individuals who are known **not** to have elevated IgG antibodies to egg are tested with that method, only 70 of those 100 people will be reported as having no antibodies. For the remaining 30%, their "abnormal" findings are a misleading false positive. That is, they do not have the condition, but were falsely reported as having it. This may result in those patients being put on a therapy for something they do not have. The more specific a test is, the fewer false positives it produces. In summary, a false positive reports the presence of a condition or disease that a patient does not have; tests with a high rate of false positives have poor specificity.

Clearly, tests that have poor specificity and/or sensitivity are of less value in correctly diagnosing a patient's condition.

Non-analytical factors are also important in predicting the usefulness of a test. They fall into two main areas: *pre-analytical variation* and *within-subject (normal) biological variation*. Pre-analytical variations are factors affecting a test's result that exclude the actual performance (precision and accuracy) of the testing protocol itself. Pre-analytical variation can be affected by sample collection, storage, transport, type of sample, and even such things as tourniquet application (in the case of blood samples). For example, whether a sample degrades at room temperature may be a significant pre-analytical variability in the

test results. Laboratories should perform various tests on samples, including shipping, temperature changes, and collection variations, to determine how and whether pre-analytical variation can be limited.

Biological variation (within-subject variation or intra-individual variation) involves normal day-to-day variations in an analyte caused or affected by circadian rhythms, sleep-wake cycles, food intake, physical activity, time of year or season, stress or anxiety, and concurrent illness. For example, the assessment of high sensitivity C-reactive protein may be affected by seasonal allergies. Therefore, its evaluation as a marker for cardiovascular disease in an individual patient may be problematic unless this biological variation is accounted for.¹⁴ Biological variation is of critical importance for the laboratory to determine; without that information, the clinician has little idea if the change in analyte being measured is significant (secondary to therapy) or random. If serum cholesterol, for example, had a known variation depending on time of year, a measurement in January might be significantly different from one in June, not because of any therapeutic intervention, but because of the natural variation from winter to summer. While this is not the case with cholesterol, there are many analytes for which biological variation has not been determined, or has been determined and has shown wide variation. Biological variation is determined, in general, by collecting a series of samples from a group of participants at regular intervals, minimizing pre-analytical and analytical variation, storing samples for batch analysis later, analyzing samples in duplicate, removing outliers, and then determining within-subject (biological) analysis of variance.

It is vital for those involved in laboratory testing to minimize analytical and pre-analytical variability and to measure and report biological variation. One must consider the influence of these factors on laboratory tests and on the interpretation of laboratory results. Clinicians considering the use of new or unfamiliar tests should request information from the laboratory on all the factors discussed above, and should examine the data before relying on the test for clinical decision making.

Identifying Practical Interventions that Help to Normalize Multiple Symptoms

Nancy Sudak, MD, and Virginia Shapiro, DC

The initial functional medicine approach involves foundational recommendations that produce a positive impact on multiple systems. Many of these interventions have been extensively discussed and documented in the preceding section of this book (A Practical Clinical Approach), but still we are left with the question of how and where to begin with a particular patient. Looking for the simplest interventions that will achieve maximum impact is a reasonable starting point. Although these initial interventions may sound very basic, patients are typically quite pleased to find that implementation can produce a dramatic enhancement of well-being.

It is clear that our daily behaviors have a large impact on our health. Patients seem to understand the relationship between diet and physical activity as they relate to common diseases. We are aware of abundant evidence that dietary measures can reduce the incidence of adult onset diabetes; lifestyle changes have been shown to meaningfully outperform metformin in generating a higher rate of diabetes prevention.^{15,16} Secondary prevention of myocardial infarction has also been demonstrated dramatically by dietary interventions involving omega-3 fatty acids in the GISSI Trial,¹⁷ the DART Study,¹⁸ and the Lyon Study.¹⁹ The functional medicine style of practice teaches patients that their daily choices have a powerful effect on their health. Therefore, in-office patient education (a very important, albeit basic, intervention) is a critical factor in achieving success with lifestyle changes. The functional medicine model requires active patient participation, and may be challenging for those expecting passive delivery of health care.

Numerous lifestyle modifications of benefit to the patient are likely to be identified early in a functional medicine work-up. Many such changes are already familiar to most patients as recommended healthy practices, but they have not been adopted for a variety of possible reasons: unpreparedness for change; belief that low-tech interventions are unlikely to have a measurable effect; insufficient understanding of how lifestyle habits affect health; and home or work situations with little support for changing behaviors. When a practitioner or patient educator thoroughly and non-judgmentally explains the basis for lifestyle recommendations relative to the individual's specific situation, a

door opens for patients to meaningfully reevaluate their daily actions.

Patients need information, instruction, and ongoing support as they integrate untried practices and abandon comfortable habits that have long undermined their health. An integral element of the art of practicing functional medicine is the ability to encourage patients without overwhelming them. An overzealous functional medicine practitioner or educator may impair the therapeutic relationship by mandating too many changes simultaneously, when a given patient may already be struggling to put new principles into operation.

No two patients are treated identically in functional medicine, but some advice is applicable to nearly every patient. The following lifestyle recommendations also meet the criterion of helping to normalize multiple systems and thus provide a better foundation for health:

- Removal of processed foods and *trans* fatty acids
- Ingestion of healthy whole-food meals at regular intervals
- Increased intake of vegetables, with moderate fruit intake
- Consumption of organically raised and locally grown foods whenever possible
- Achieving balance of macronutrients
- Removal of potential or documented food allergens
- Adequate daily intake of essential fatty acids, fiber, and pure water
- Deletion of toxic influences (including, for example, household pesticides and herbicides, toxic household and personal cleaning products, and certain cosmetics)
- Inclusion of exercise, stress management techniques, and spiritual centering in daily life.

As functional medicine practitioners, we know that poor diet, toxic overload, and overstimulation of inflammatory mediators impair proper function. Consistent application of healthier lifestyle habits optimizes broad areas of function by minimizing metabolic demand. When we restore nutrient adequacy, reduce toxic burden, and diminish excessive activation of the hypothalamic-pituitary-adrenal (HPA) axis, metabolic efficiency is more likely to normalize. Patients who have been effectively instructed on these concepts often establish early improvement of symptoms before more specific and advanced interventions are suggested.

For example, when women with a variety of menopausal or perimenopausal symptoms implement basic lifestyle modifications, they tend to report improvement in bowel function, energy, mood, and general sense of well-being, as well as reduction of myofascial pain, and diminished frequency/intensity of headaches and hot flashes. When patients with extremely complex disorders and imbalances make similar changes, they often achieve substantial, sometimes astonishing improvements in their physical conditions. The power of lifestyle modification in complex illness should not be underestimated. When these measures alone are ineffective in removing barriers to proper function, further investigation and treatment are warranted.

The following case example illustrates a patient with multiple and complex areas of dysfunction and her response to some fairly simple initial interventions.

A 57-year-old woman visited our office with a chief complaint of active ulcerative colitis of 3.5 years' duration. Colonoscopy revealed extensive ulceration of her colon; multiple medications had been used unsuccessfully or were not tolerated; and her gastrointestinal specialists had stated that colon resection appeared to be her only viable long-term treatment option. Additional medical problems included osteoarthritis of her neck and right shoulder for 14 years and hypertension.

Five years previously, she had traveled overseas and returned with abdominal bloating and diarrhea, acute diffuse joint pain (reactive arthritis), iritis, and urethritis. She had been diagnosed with probable giardiasis (negative stool study) and Reiter's syndrome, experiencing symptom resolution with antibiotics. One year later, her diffuse joint pain recurred, and rofecoxib was initiated. Shortly after the addition of this medication, classic symptoms of ulcerative colitis occurred, and she was treated conventionally, without any correlation made between her colitis and the cyclooxygenase (COX)-2 inhibitor. Her medications at the time of presentation in our office included rofecoxib (4 years), atenolol (5 years), mesalamine (3 years), and mercaptopurine (1 year).

Our initial clinical assessment indicated gastrointestinal inflammation, altered intestinal permeability, and mild dysbiosis of her gastrointestinal flora. We advised a basic approach, including trial elimination of gluten grains and dairy products, avoidance of refined sugars and *trans* fatty acids, macronutrient-balanced diet, and implementation of the general bulleted recommendations itemized above. She was also started on EPA/DHA

fish oil, vitamin E, zinc, carnosine, 5-methyltetrahydrofolate, a probiotic supplement, L-glutamine, and an herbal anti-inflammatory product containing extracts of hops, rosemary, and olive leaf.

After two months, her bowel function, energy level, and sense of well-being were dramatically improved. Her blood pressure had normalized and atenolol was discontinued. rofecoxib was completely withdrawn by month four, and relief from osteoarthritis symptoms was maintained with adjunctive chiropractic care and frequency specific microcurrent therapy. She has had no recurrence of her reactive arthritis. She was eventually able to discontinue the mesalamine and mercaptopurine, and remains free of gastrointestinal symptoms over a year after initial interventions in our office.

The functional medicine approach successfully addressed her underlying inflammatory dysregulation and ultimately spared her from a total colectomy. This case is also an example of the complexity of many cases seen in functional medicine practices, in which multiple causative factors occur in layers (including iatrogenic influences). In such cases, simple initial interventions may or may not result in such complete results. When symptoms continue, patience and persistence are required as the astute clinician learns to tease apart the various components of the patient's condition to determine underlying causes.

The elimination diet (discussed earlier in this chapter) is an example of a therapeutic strategy (with a diagnostic component) that tends to produce improvement in multiple systems.^{20,21,22} Patients with numerous symptoms who are employing a standard American diet often benefit from a comprehensive elimination diet, in which commonly irritating foods such as gluten grains, dairy products, corn, chocolate, peanuts, and eggs are avoided for a period of several weeks. Relief from symptoms such as migraine headaches,^{23,24} fatigue, body aches, mood disturbances, irritable bowel complaints,^{25,26} dermatitis, and perennial rhinitis²⁷ is typical during the elimination phase.

A principal mechanism underlying symptom resolution in many cases is reduction of inflammatory activation from offending foods. It is helpful to consider the central location of most of the immune system—within the gastrointestinal tract. When antigenic exposures to foods mismatched to an individual's physiology are removed, physiologic function improves. If patients find that systematic reintroduction of foods, one by

one, indicates several intolerances, a functional medicine practitioner will consider the likelihood of altered intestinal permeability. Reasons underlying the passage of large molecules through the gastrointestinal mucosa will then have to be explored. (Chapters 28 and 31 provide detailed information on intestinal permeability.)

When we decipher a patient's story by constantly asking why a condition has emerged, we may eventually reach a core dysfunction that can be remediated. The process of prescribing this "simple" intervention, the elimination diet (with its diagnostic and therapeutic elements), may be represented by the scheme shown in Figure 35.1.

Figure 35.1 Schema for use of elimination diet

In summary, it behooves functional medicine practitioners and their patients to carefully consider foundational lifestyle practices when making initial assessments of patients with complex disorders or health histories. It has frequently been our experience that many medications can be reduced or eliminated through simple lifestyle modification. This should not, however, diminish

the importance of thorough evaluation of the patient, appropriate to their specific condition and to the credentials and training of the practitioner. Basic changes in dietary and exercise practices can often be implemented in conjunction with more conventional treatment. In addition, many foundational lifestyle changes can be initiated without harm, while more in-depth investigations (laboratory, radiology, or others) are pending. The patient's response (or lack of response) to these basic interventions can often provide additional diagnostic information to the astute clinician, as well as provide the patient with encouraging relief of symptoms.

Chapter 36

The Healing Relationship

- ▶ *Creating Effective Doctor-Patient Relationships*
- ▶ *Helping Patients Change Unhealthy Behaviors*

Creating Effective Doctor-Patient Relationships
Edward (Ted) Leyton, MD, CCFP

Introduction

In the Introduction to this book, we read the following statement:

Functional medicine could be characterized, therefore, as “upstream medicine” or “back to basics”—back to the patient’s life story, back to the processes wherein disease originates, and definitely back to the desire of healthcare practitioners to make people well, not just manage symptoms.

This begs the question of how clinicians can obtain enough of the right kind of information from patients in the relatively short period of time we are in contact with them. Patients have lived a lifetime of experiences, some good, some bad, some with significant impact, and some that are insignificant. How do we put all of this together in a frame that helps us mold a functional diagnosis and treatment plan? It has been said that 90% of all diagnoses in medicine are still made on the basis of history, symptoms, and review of systems—although we would add review of mechanisms to that list (see Chapter 34)—and that technological investigations, though frequently helpful, are most often illustrative and additive.¹

In this chapter—indeed, in this whole section of the book—we are learning how to elicit, organize, and use information about the antecedents and triggers that precede the onset of symptoms, and the mediators that keep the dysfunction going. Antecedents and triggers can be amazingly diverse, ranging from motor vehicle accidents to sexual abuse, from toxic exposure and fam-

ily history to limiting decisions and beliefs that patients have adopted from an early age regarding their lives. The ability to glean this information from the patient is critical to weaving the interconnected web that is so basic to the functional medicine model.

Therapy actually begins from the moment the patient enters the clinic. From the atmosphere in the waiting room to the physical posture, attitudes, beliefs, and language of the practitioner and staff, there is always a need to foster in the patient an awareness of what it means to view health as positive vitality.

Rapport

To elicit and understand the patient’s story, to help people make changes that are beneficial, and to create a healing relationship, it is important to be able to develop a rapid and powerful rapport with patients, so they feel comfortable telling their stories and revealing intimate information and significant events. Rapport is the core element that enables a practitioner to glean this kind of information from patients. Without rapport, both the functional diagnosis and treatment recommendations may be flawed or ignored. We will examine the following elements of the successful doctor-patient relationship:

- What is rapport and how can it be established rapidly and respectfully?
- What questions elicit the information needed to weave the functional web or matrix, so that treatment can be successful?

- What language empowers and motivates patients in a movement toward positive vitality and wellness?
- How do we de-emphasize the pathology model to which we are accustomed?
- How do we help patients change their behaviors and lifestyles so they feel empowered, fully functional, and able to manage on their own to a large degree?

What Is Rapport?

Being in rapport is the ability to enter another person's model of the world, communicating that we truly understand that world, in a **congruent** way. Being congruent means that we express ourselves with all our senses in a unified way. You have been establishing rapport unconsciously all your life; we all learned this as we figured out how to get along with people. Now we can enhance this process by making it conscious.

In functional medicine, patients are seen as unique individuals who may not fit the pre-determined models that correspond to particular diseases or conditions. Rapport will help us elicit, in a short space of time, the patient's complete story so that we can begin formulating a treatment plan. Traditional diagnosis is usually a part of the story—at least at the outset—but it is not a primary goal, and it will not tell the full story. The initial goals are to gather information that will help to create an *individualized* picture of the patient, create a working hypothesis about the dysfunctions underlying the symptoms and complaints, and form an effective, professional bond with the patient.

Presuppositions

Presuppositions about our patients set the stage for a positive or negative relationship, and they can interfere with establishing rapport. What *you* believe will influence the course of the patient's illness or wellness, if not at the conscious level, then certainly at the unconscious level. This is demonstrated eloquently in Daniel Moerman's *Meaning, Medicine and the 'Placebo Effect,'* wherein he explores and explains the research about placebo.² Moerman argues that it is not so much the patient who produces the placebo effect, but rather the healthcare practitioner whose beliefs about the treatment or the patient have considerable influence on the outcome. Here are some *helpful* presuppositions (assumptions) to have about all patients:³

- **Patients have all the resources they need to heal.** Clearly they may not have the same *knowledge* as you do about biochemistry and metabolism, but remember that they live in their bodies, and they have had to learn many things in order to survive and function.
- **The meaning of your communication is the response you get.** If a patient gives you a signal (verbal or non-verbal) that something you have said or done has triggered a negative emotional state (see below), use that information as feedback for a different approach, because ...
- **Your personal flexibility will determine your success.** If something you are doing or saying isn't working—change it. Systems theorists have shown that the system with the most flexibility is the one that generally ends up working.⁴
- **Every behavior has a useful purpose in some context.** Patients with chronic illness sometimes develop illness behavior, which you may have learned to view as a negative trait. Remember that this behavior **serves some useful purpose** (usually unconscious) for the patient. Understanding this will help you avoid the trap of labeling anyone as a "problem patient."

Emotional States

An emotional state is a *particular way of feeling*, brought about by internal representations and physiological shifts, as a result of a person's life experience, conceptual filters, and internal map of reality, at that moment, and in that context.

Emotional states can range from depression to elation, with myriad possibilities in between: aggravation, frustration, excitement, boredom, joy, amusement, grief, and so on. Emotional states are internally generated by information that comes to us through the five senses—visual, auditory, kinesthetic, gustatory, and olfactory. The information is then processed through a variety of unconscious filters that ultimately create an internal representation of what we see, hear, taste, smell or feel. Such representations have the power to create a shift in a physiological state and can influence subsequent behavior.

A simple example will illustrate. A man is driving home on the highway from work after a stressful day. His mind is filled with thoughts about his day and anything that may have precipitated unpleasant feelings

that we generally characterize as “stress.” Perhaps he has a headache, neck pain, or stomach ache. As he looks out of his car window, he sees (visual representation) the sun setting in the west. He is reminded of his last vacation (past experience), when he saw a beautiful sunset, and he recalls the closeness that he felt with his wife as they watched it from their hotel balcony. As he “connects” to this past experience, he can feel his shoulders relaxing and the tension easing from his body (kinesthetic shift). This man has just changed his emotional state, fortuitously on this occasion, by changing his focus of attention and by remembering a pleasant past experience.

Most patients are in what we might call a *problem state* when they see us. They feel bad. They have to feel that way in order to communicate effectively about their problems—in other words, they have been thinking about the problem and how they are going to describe it. They have been internally rehearsing prior to the visit.

An important factor to take note of here is that we—the practitioners—are also in some kind of emotional state, and whatever it is will surely affect our interaction with the patient. So, it’s good to take stock: **Consider what kind of state you are in before you see the patient.** Are you in a bad mood, or stressed out? Did the last patient trigger some bad feelings? Do you have some personal matters you are bringing to the interview? Or, on the positive side, are you relaxed, curious, and eager to discover something unique about the person you are about to see? If so, you are in an excellent state for seeing patients.

You can help yourself achieve that positive state. Remember a time when you felt **really curious** about something. Mentally imagine yourself being curious, hear what you are saying to yourself, and feel the change in your body as you do this exercise. Take a few deep breaths to relieve any tension you might have, and then greet the patient with a genuine, flexible, curiosity. This will go a long way toward building rapport and establishing a comfortable ongoing relationship with your patients.

Communication

Communication is 7% words, 38% tonality, and 55% physiology. As mentioned above, we all use our senses to take in our experience of the world. Research has shown that we use the following percentages of our senses to map our reality:⁵

- Visual—60%
- Auditory—20%
- Kinesthetic—20%
- Olfactory/gustatory— <1%

Therefore, your patients will be communicating problems to you with many of these senses, although most of us have a preferred style—most often visual, then auditory and kinesthetic.

Let’s look at this a little more closely. Since we all take in the world through our senses, the type of sense we use will depend on the circumstances. For example, at a concert, the primary sense is tuned to the auditory channel. Looking at a painting requires a visual focus. Doing a workout requires a kinesthetic sense of body position and movement. When we communicate with others, we also *express ourselves* in one or more of these senses:

Sometimes when I sit out on my deck I feel really fulfilled and content. I can **see** the vibrant colors of the blooming flowers, **and hear** the gentle trickling of the waterfall in my pond. Further off in the distance I can **hear** the fluttering of bird’s wings as they play in the birdbath, while a gentle breeze **wafts** across my face bringing me the **sweet scent** of July blooms.

What’s missing from this paragraph? Tonality and physiology are missing, and if you read this to yourself, you will fill them in automatically, based on your own experience. But notice that in this example the verbs or descriptive words match the nouns—that is, you see colors, hear the trickling-fluttering; feel the wafting breeze. This matching helps make the passage *congruent*. However, congruence also depends upon *tone* and *physiology* even more than the choice of words. Sarcasm is a good example of how this works—a sarcastic comment is one in which words, tonality, and expression are not balanced: “I *really* like your tie” (*sneer*). What do we tend to believe? The tone and the visual cues. If the comment is more veiled, we may just feel uneasy, or think that something “isn’t quite right.”

Obviously, this is important information to have, both in the context of what you hear patients saying, and how you say things to them. Some people select primarily **visual** language: “I *see* what you mean.” “This *colors* my judgment.” “You can *look back* on this material and notice how easily it comes to you.” Others choose **auditory** images: “I *hear* what you’re saying.” “That *rings* a bell.” “This idea is coming across *loud and clear*.” Still others use **kinesthetic** words: “I can’t *grasp* that.” “*Hold on* a minute!” “I’m *going to pieces*.” “I think I *have a handle* on this now.”

With this information in mind, we now turn to the development of patient rapport.

Establishing Rapport

People tend to like people who are like themselves. When we meet someone new, we search for **commonality**. Rapport is created and established by pacing the individual’s communication through **mirroring and matching** the key elements of a person’s **physiology**—gestures, facial expressions, eye blink, breathing; **tonality**—tone, tempo, timbre, volume, pitch, pauses; and **words**—predicates (verb phrases), key words, associations.

- You know you are in rapport when:
- 1. You are getting the outcome you want (that might be just getting along with the patient or making the patient feel comfortable), and
 - 2. You calibrate to the person’s level of comfort—that is, you keep the level of comfort relatively steady and, if discomfort arises in the patient, you change your approach so that rapport is re-established. (Sometimes when you have sufficient rapport, the relationship can tolerate a certain amount of discomfort. However, handling discomfort in the relationship is beyond the scope of this text.)

There are clearly varying degrees of rapport, as shown in Figure 36.1. In professional relationships, optimum rapport is defined in a fairly narrow band. It is important to avoid overidentification with the patient (and his or her problem) and still be able to communicate understanding and empathy. Physicians are often taught to aim for a cooler demeanor, to avoid getting “too involved.” Unfortunately, this can result in a lack of rapport, generating frequent complaints from patients. In my practice, I often hear that other physicians “don’t care about me, and don’t listen to my concerns.” I feel confident that usually the other physician does care, but because of our professional training, he or she may equate objectivity with emotional distance or coolness. I believe that maintaining understanding, openness, and empathy *without overidentification* is critical. Clinician/patient boundaries are important; clinicians must recognize that there are limits to their responsibility to and for the patient. Boundary issues regarding overidentification and sexual/romantic connections with patients are beyond the scope of this text, but have been dealt with adequately elsewhere.⁶

Figure 36.1 Degrees of rapport

Behaviors and Skills that Build Rapport

In order to build rapport, you need to develop sensory acuity. The more sensory acuity you have, the more you can calibrate to the patient’s nonverbal but significant communications. We gain sensory acuity by watching, listening, and occasionally smelling and touching our patients. We use many of our senses to communicate, and also to calibrate to our patient’s state. When we calibrate well, we can shift our behavior to **match and mirror** the patient, in order to gain more rapport. This is called *pacing current experience*.

Pacing current experience. You can learn how to match and mirror your patient’s words, tone, and physiology, and thus gain sensory acuity *and* rapport at the same time. People feel more comfortable with someone who responds to them in the *same language representations* that they are using. This will lead you rapidly into a state of rapport that can—seemingly magically—produce a wealth of information in a short time. The following characteristics of certain people will help you to determine their primary representational system.

Primary Representational System	Characteristics Displayed
Visual	Thin, ectomorphic, wiry, wide-eyed, fast talkers, neat, chest breathers
Auditory	Mesomorphic, easily distracted, very verbal, even breathers
Kinesthetic	Endomorphic, lax in dress, slow talkers, diaphragmatic breathers

Pacing and then ... leading. With pacing, you begin to establish more rapport. Once rapport is established at a sufficient level, you can begin to **lead** the person. Leading is a mild challenge—have you ever paced a friend who was training to run a certain distance in a certain time? If you ran slightly ahead of him (or her), you would induce him to run faster to keep up, and then you could pace him again by running beside him. In interviewing and psychotherapy, leading may be used to help a person feel more comfortable in their surroundings, or to move them from a non-resourceful emotional state to a resourceful state. The overall process for establishing rapport through pacing is shown in Figure 36.2.

Figure 36.2 The process of establishing rapport

Matching is an integral part of pacing and rapport building. Table 36.1 reviews the different ways in which matching can be done.

Table 36.1 Matching Behaviors

Type of Matching	Behaviors
Whole Body Matching	Adjust your body to approximate the patient's postural shifts, e.g., cross legs, adjust torso angle, etc.
Partial Body Matching	Pace any stylistic use of body movements, e.g., eye blink, head shakes, head/shoulder angle, etc.
Vocal Qualities	Match shifts in tonality, tempo, volume, timbre, cadence or intonation.
Verbal Patterns	Hear and utilize sensory system language that matches and paces the representational system used by the patient (i.e., auditory, visual, or kinesthetic language).
Facial Expressions	Notice the patient's facial expressions—wrinkles, lips, eyebrows, etc.
Gestures	Respectfully match the patient's gestures.
Breathing	Adjust your breathing pattern to match the patient's.
Matching is NOT copying. All of the above must be below the client's level of awareness.	

Understanding the Story—Some Questions to Ask

Patients often provide clues about important factors in their stories in ways that can sometimes be easily overlooked when we focus too much on physical vs. emotional content. Open-ended questioning, together with listening in a non-judgmental way, will provide us with the opportunity to **really** hear what the patient is saying. Here are some open-ended questions that can elicit very useful information:

1. **When did you last feel really well?** This is an extremely important question because it takes the patient back to a time before things changed from good to bad. The answer may elicit both the temporal onset of symptoms and the **triggers or antecedents** for the functional issue. Asking the question in

this way, as opposed to focusing on when the patient began to feel sick (a more standard inquiry), requires patients to access, in memory, a time when they felt good, and that may give you important information that will help you to manage their “wellness program.” If there were only one question that a clinician could ask, it might well be this one. Ensure that you do initially elicit a **wellness** description here, as it is likely that the patient will gravitate to an illness description in order to tell you what is wrong, purely out of cultural conditioning.

2. **What happened then?** This is the next question to ask because you want to elicit a sequential response that will maximize the possibility of accurately identifying antecedents and triggers. Depending upon the patient’s particular way of telling stories, you will get more or less detail. Sometimes you may have to curtail too much detail, and at other times you may have to fish for more detail, remembering that you are looking for clues about triggers and antecedents.
3. **Was there anything going on in your life at that particular time that might have precipitated this [illness, pain, or other symptom]?** This question allows the patient to connect symptoms of any kind with stresses or life changes that they may have experienced. It gives them permission to make, or recall, that connection.
4. **Do you think that this [illness, pain, or other symptom] had anything to do with the fact that you [had a car accident, lost your father, became unemployed ... insert the specific event you are inquiring about]?** Again, this gives the patient permission to make connections between possible antecedents or triggers and their present symptoms. If they do make such a connection, the chances are it has some validity in their model of the world.
5. **Did anything happen to you as a child that made you feel bad?** This question is very open-ended, and may yield a number of results. Some patients may simply answer “no,” in spite of the fact that such an answer is unlikely to be correct, since most people can recall at least one bad thing that happened to them during childhood. The “no” answer may have two possible reasons: perhaps something did happen that they don’t want to talk about, or, in their map of the world, they simply don’t include “bad things.” Both of these have to

be respected. I sometimes preface this question, particularly in patients who are presenting with gastrointestinal issues, in the following way:

There is research showing that some people with long-standing intestinal problems have had abuse issues as children. I don't want to suggest that that might have happened to you, but I do need to ask ...
Did anything happen to you as a child that made you feel bad?^{7,8}

You may be thinking, “What do I do with this kind of information if I get it?” The answer will depend upon your particular clinical skills, focus of interest, and degree of comfort with exploring such issues. For those with appropriate training and interest, affirmative answers to any psychological questions can be explored further for the purpose of healing. That work may not be appropriate for an initial intake and may be deferred to future sessions; this of course should be communicated to the patient. For clinicians with less training in this area, it is important to support patients in some way when they disclose triggers of a sensitive nature. This might take the form of acknowledging the importance of the connection, followed by suggestions for appropriate therapy and follow-up with a professional trained in the area. For example:

This is obviously a sensitive and important area, and may have an impact upon your ultimate recovery. In the functional medicine model, these emotional factors can have a significant negative impact on our overall well-being. Would you be willing to talk to someone whose training could help you resolve any lingering issues that you might have with regard to this problem?

Raising questions in the way described above gives the patient the opportunity to engage with difficult issues or to bow out without feeling pressure. It is also helpful to give them a future option such as, “Feel free to talk to me about this again if you change your mind.” All too often, patients have not been given the opportunity to even mention such matters in a practitioner’s office, let alone been given the opportunity to consider a solution.

You might wonder whether asking these kinds of questions could raise issues that are better left alone; in other words, is re-opening old wounds a good idea? I frequently find that the patient has made these connections anyway, and is relieved to know that a professional sees the importance of them. Sometimes just acknowl-

edging this can provide such significant relief that nothing more needs to be said. This is the power of a really effective doctor/patient relationship—it becomes a healing relationship.

Motivation, Changing Behaviors, and Feedback

Language is really how we measure experience, and how we re-present our experience to others. Since our primary goal as practitioners is to help people feel better on many levels, it is important to use language that is positive and, at the same time, an honest appraisal of the situation. Transmission of hope to the patient is often essential to a good outcome.

Healing language encompasses:

- Self-empowerment
- Direction
- Motivation and feedback

Whatever the particular problems of your patients, the chances are that some aspects of their behavior will need to change in order for them to feel better. Changes may relate to diet, exercise patterns, stress management, leisure activities, or some other behavior. The functional medicine practitioner is in an advantageous position with patients because the model not only allows, but demands, that we take advantage of this “teachable moment.” The functional medicine model is a generative one, in which new behaviors lead to feeling better emotionally, physically, and spiritually.

It is a good idea to assume that patients are willing to change their behavior in order to feel better. They need to begin at the appropriate “stage of change” (the subsequent discussion in this chapter addresses that topic in depth); fortunately, if that need is met and real help is offered, great progress can be made. While it is true that there are some patients with recalcitrant, addictive behaviors, it is also true that even these people usually want to change for the better. If we see a patient as an addict, rather than as someone who is capable of changing an addictive behavior, then the label “addict” tends to reinforce the belief that the condition is immutable. How can the practitioner in a general functional medicine practice help people change their unhealthy behaviors?

Motivation

People are motivated by a variety of factors. Often what brings people to practitioners is the fear of an incurable or painful condition. This at least gets them in the door, and indeed it may be a powerful motivator to do something different. However, as the person who is motivated by fear begins to get better, the impetus for the motivation decreases because the fear is no longer there. One very important factor is to ensure that the patient also has a positive **future** motivation, as well as a motivation to **move away** from the problem. You can access the desire for something positive in the future by posing some of the following questions:

- Tell me what it will be like when you are free of this problem?
- What will you be doing that is different?
- How will you be feeling that is different from the way you are feeling now?
- How will other people see you differently?
- How do you think I can help you, and what kinds of resources do you need?

Asking these questions requires that patients conceptualize future associations with wellness to sustain the changes in their lives even after fear and pain have subsided. When a patient is close to achieving initial goals, he or she can be helped to create other goals that can strengthen their motivation for the long term.

Different people motivate themselves in different ways. Here are some **unhelpful** motivational styles, as outlined by Connirea Andreas in the book, *Heart of the Mind*:⁹

- **Overwhelm motivators** often select a huge goal and make it so big in their minds that they are actually unable to get started because the goal overwhelms them. If you ask what the goal “looks like” to them, they will tell you that it is very large and occupies a lot of their mental space. No wonder they feel overwhelmed. With these people it is a good idea to “chunk down” their goal into smaller, more easily obtainable portions. With weight loss, for example, aiming for small consistent losses over shorter periods of time is more effective than talking about a large weight loss over a longer period of time.
- **Dictator-style motivators** tend to talk to themselves in a negative way using language that is authoritarian and demanding. They don’t get things

done because there is often a rebellious response to such demands. Generally people don't respond well to authoritarian approaches, even their own! Helping such patients create more respectful inner dialogues about their future goals can be helpful.

- **Seeing-it-done motivators.** Have you ever had trouble motivating yourself to do something you like? Probably not. We don't usually have to motivate ourselves to go to a movie, eat a meal, or go on vacation because these activities, for most of us, are enjoyable. We imagine doing them and we feel good. However, when it comes to doing the dishes, tidying our desks, or cleaning the house, the very thought can be unpleasant. The trick here is to visualize having it *done*. Seeing the house tidy, the dishes clean, the desk organized—or the exercise completed, vegetables in the refrigerator, a healthy meal actually on the table—can create a positive impetus.

Of course, these patterns are not mutually exclusive; they may vary from one context to another within a single individual. Figure 36.3 shows a general pattern for helping patients to motivate themselves.

Figure 36.3 Motivating patients

In words, it might be phrased this way:

Pick a goal in the future that you want (e.g., weight loss). See yourself having accomplished that goal now—you are a healthy weight, wearing the clothes you like, and doing the things you like to do. Tell yourself in an encouraging internal voice how good you will feel when you get there, and how you will notice changes almost immediately that are small but pleasant. Remember to see yourself having accomplished the task. If that is too overwhelming, then see the first step clearly in your mind, and move on to each successive step as you are able.

Remember, motivating patients—and ultimately helping them to find their own effective motivation—is essential for a good outcome. People often feel overwhelmed at the thought of changing the habits of a lifetime, especially around food and exercise. However, remember that people are motivated when they enter your office. They may already be looking for a different approach and may expect you to recommend actions they can take on their own behalf, so they are primed. If you present, in an attainable way using some of the concepts outlined above, a plan for change, you enter into a partnership with them for achieving desirable goals. I find working with nutrition excellent in this regard because it often works quickly. If I have formulated the problem correctly, and the patient has carried out the instructions faithfully, by the next visit (two weeks), many patients find their symptoms have improved by as much as 50%. The Medical Symptoms Questionnaire (see Appendix) can be used as an objective measure of improvement if you ask your patients to fill it out at regular intervals. Patients can see how much better they are in black and white, so to speak. A sense of accomplishment is, in itself, a powerful motivating force.

General Language Guidelines and Giving Feedback

There is, of course, much more to be learned about how health professionals can communicate effectively with patients. Further reading from the references, or focused training, will help you move beyond this introductory information. A very useful book in this regard, particularly for health professionals, is *Irresistible Communication: Creative Skills for the Health Professional* by King, Novik, and Citrenbaum.¹⁰ Although this book is both out of print and a little dated in its approach, it contains a wealth of useful information for communicating with patients in the healthcare setting, with excellent examples.

In thinking about the language we use with patients, it is helpful to remember that language consists not only of words strung together into sentences—we also group sentences into paragraphs or blocks of words to expand and enhance meaning. And, in oral communication, there is the final nuance, the unique way in which words and sentences are spoken (and heard), with differences in tonality, pitch, and speed, and accompanied by facial expressions and other physical

manifestations. It is this complex structure that imparts such meaning to the words themselves.

In the old paradigm, we might have spoken to a patient in the following way regarding, for example, irritable bowel syndrome:

We have performed all the tests and they are all negative—we couldn't find anything wrong. This means you have something called irritable bowel syndrome. IBS is common; we really don't know what causes it; and there is not a lot we can do about it. You may have heard that it is caused by food allergies, but there really isn't any hard evidence for that, so I wouldn't avoid particular foods. You can eat what you want. You should increase your fiber intake and use bran or Metamucil®. Drink lots of fluids. Relaxation is sometimes helpful; take a few days off and relax. But stress doesn't cause the disease. You will likely have this for the rest of your life. I can give you some medication for the pain, and I'll see you again in a year to see how you're doing.

All too often, this is actually a paraphrase of what is told to patients. The most common complaint I hear from patients is that they feel hopeless about this condition, and the specialist did not listen to any of their ideas about it.

Strictly speaking, what has been said in the above example is mostly true (albeit incomplete). But, we should ask ourselves, in any patient encounter, “What is my intention?” If our intention is to have the patient feeling better, then the above language needs to change.

Here is my critique of this approach:

- *We have performed all the tests and they are all negative—we couldn't find anything wrong.* Implies to the patient that there is something wrong, but we couldn't find it, OR there is nothing wrong and therefore, “Why are you complaining?”
- *This means you have something called irritable bowel syndrome. IBS is common; we really don't know what causes it; and there is not a lot we can do about it.* Sets the patient up to feel hopeless.
- *You may have heard that it is caused by food allergies, but there really isn't any hard evidence for that, so I wouldn't avoid particular foods. You can eat what you want.* Implies the patient can eat anything with impunity—the patient probably knows better, but may likely accede to the specialist/expert. Very few of us can truly eat exactly what we want.

- *You should increase your fiber intake and use bran or Metamucil®. Drink lots of fluids. Relaxation is sometimes helpful; take a few days off and relax.* Implies that relaxation is easily accomplished, instead of a skill to be learned. Does not address dietary approaches to increasing fiber, which can have many other benefits as well. Using approaches that help to normalize multiple systems is efficient and effective.
- *But stress doesn't cause the disease.* Implies, therefore, that stress is not really important.
- *You will likely have this for the rest of your life.* In hypnosis, this is called an embedded command—it can create a powerful negative suggestion at the unconscious level.
- *I can give you some medication for the pain, and I'll see you again in a year to see how you're doing.* Some patients interpret this as a brush-off, and it certainly doesn't create a sense of partnership in addressing the problem.

Overall, this is not an empowering communication:

1. **It provides less information than there really is about the condition.** There are approaches that can improve IBS; a number are discussed elsewhere in this book. There are dietary changes that can have multiple benefits. Training in stress management and relaxation is widely available and can be very helpful. For some patients, food sensitivities can be a problem; an elimination diet might help discover if that is the case. Exercise may help certain patients, and supplementation may help others.
2. **It leaves the patient feeling powerless.** If patients are empowered, they can be extremely effective partners in identifying triggers and mediators for this and countless other conditions. You want them working with you (and for themselves).

There are some guidelines for using language as a tool to create the outcome you and your patients want:

- **Tense.** People with chronic illness are often stuck in the past. They wish “it” hadn't happened, or it could have been different. Your language can bring them into the present and on into the future. Remember to move them forward: “What you are doing **now**, by changing your diet, will help you to feel better in the **future**. Let's imagine what that will feel like so that it becomes real for you.”

- **Unconditional presuppositions.** Use **when** rather than **if**. “If” implies doubt that it might happen; “when” presupposes that it will happen—it’s just a question of time and effort. For example, “**When** you start your nutrition program, you will”
- **How or what, rather than why.** “Why” questions generally get us into trouble and don’t lead anywhere except to more generally unhelpful information. “How” questions provide more useful information. So if a patient says, “I haven’t been able to do the diet, it was just too much for me,” don’t ask “Why?” because that invites a list of excuses. Ask, for example:
 - “How did you actually stop yourself from starting the diet?”
 - “What would make it more likely that tomorrow you can take the first step?”

Answers to these questions should give you more information about how to help patients overcome the obstacles they have named.

- **Offer choices** that help the patient to focus on specific times and actions. For example, if a patient is beginning a lifestyle change program, say “Will you start the (nutrition, exercise) program **before** or **after** you go on holiday?” “What day **will** you begin?” The assumption is they will start; it’s just a question of **when**.
- **Giving feedback.** The more encouraging feedback you can give, the better. Remember, your patients have been sick for a while, and they need lots of encouragement to initiate and maintain healthy changes. When you want something done differently, or you are concerned about progress, finding a respectful way to give feedback is very important. A **feedback sandwich** can work well; you sandwich any feedback that might be perceived as negative between two positive comments. For example:

I like the changes you have made to your nutrition program so far, especially the new foods you have introduced. The fact that you haven’t lost weight yet is not uncommon. It would be a good idea to replace those granola bar snacks with fruit, for more energy. And keep up the good work; you are headed in the right direction!

Summary

As you review the ideas and techniques presented so far in this chapter, keep in mind that you—just as much as your patients—are now taking on the challenge of changing your behavior as a clinician. You will need to find your own motivation and reinforcement, measure your own progress, and ask for help where needed. You will need to practice; just reading about these ideas doesn’t build the skills or the ability to maintain the new behaviors under stress. We have covered some important topics—**establishing and building rapport, creating good communication, and developing a healing language**. All of these can help us become more effective in our work with patients. If this work is new to you, then my hope is that you will be delightfully surprised and satisfied to learn, not immediately, perhaps, but after you have developed some skill, that your patients are responding in a different, more positive way, and accomplishing their goals with greater effectiveness. When that begins to happen, you will know that you are utilizing the tools that have been described in this chapter at both the conscious and unconscious level—they have become a part of you.

Helping Patients Change Unhealthy Behaviors

Janice M. Prochaska, MSW, PhD, and
James O. Prochaska, PhD

Introduction

Healthcare providers can often become frustrated by the fact that too many of their patients have unhealthy diets, are inactive, smoke, abuse alcohol, don’t manage stress effectively, and don’t take their statins or anti-hypertensive medication as prescribed. If we don’t like the way our patients are behaving, then the first thing we need to change is our own behavior. It begins by changing our mental models of behavior change. An action model has dominated medicine for more than a century. Patients are seen as changing when they quit smoking, start to exercise, or take their medications as prescribed. Action-oriented approaches are prescribed but they have little impact; for example, when healthcare systems offer action-oriented smoking cessation clinics for free, the percentage of eligible smokers who participate annually is

only 1%. We cannot impact the health of our patient populations if all we treat with the most deadly of behaviors is 1%. In this discussion, you will be introduced to a model of behavior change that can be matched to the needs of all patients and not just the minority who are ready to take action. This chapter is designed to help **you** change your mind so you can be better prepared to help your patients change their behavior.

The Transtheoretical Model of Behavior Change

The Transtheoretical Model (TTM), one of the leading approaches to health behavior change, can provide guidance in the development of interventions to increase readiness to change unhealthy behaviors. The TTM systematically integrates four theoretical constructs central to change:

1. **Stages of Change** Readiness to practice a healthy behavior
2. **Decisional Balance** Pros and Cons associated with a healthy behavior
3. **Self-Efficacy** Confidence to practice and sustain the healthy behavior in difficult situations
4. **Processes of Change** Ten cognitive, affective, and behavioral activities that facilitate the healthy behavior change

The TTM understands change as progress, over time, through a series of stages: *Precontemplation*, *Contemplation*, *Preparation*, *Action*, and *Maintenance*. Nearly 25 years of research on a variety of health behaviors have identified processes of change that work best in each stage to facilitate change.

The Stages of Change

Stage of change is the TTM's central organizing construct. Longitudinal studies of change have found that people move through a series of five stages when modifying behavior on their own or with the help of formal interventions.^{11,12} In the first stage of change, *Precontemplation*, individuals may be unaware of the negative consequences of their behavior, believe the consequences are insignificant, have given up the thought of changing because they are demoralized, or may be defensive about the need to change. They are not intending to take

action in the next six months. Individuals in the *Contemplation* stage are more likely to recognize the benefits of changing their behavior. However, they continue to overestimate the costs of changing and are ambivalent and not ready to change. Those in the *Preparation* stage are seriously considering taking action within the next 30 days, and have already begun to take small steps toward the goal. Their concern is that they will fail. Individuals in the *Action* stage are overtly engaged in modifying their problem behaviors or acquiring new, healthy behaviors. Individuals in the *Maintenance* stage have been able to sustain change for at least six months, and are faced with the challenge of sustaining the change over the long term.

Research comparing stage distributions across behaviors and populations finds that only a minority of people are in Preparation, with a majority in Precontemplation and Contemplation.^{13,14} Those data suggest that if we offered all individuals action-oriented interventions that assume readiness to practice a healthy behavior, we would be mis-serving the majority who are not prepared to take action.

Stage-matched interventions can have a greater impact than action-oriented, one-size-fits-all programs, by increasing participation and increasing the likelihood that individuals will take action. Stage-matched interventions for smokers more than doubled the smoking cessation rates of the best action-oriented interventions available.¹⁵ Stage-matched interventions have also out-performed one-size-fits-all interventions for exercise acquisition,¹⁶ dietary behavior,¹⁷ and mammography screening.¹⁸

Stage of change is generally assessed using a staging algorithm, a set of decision rules that place an individual in one of the five stage categories based on their responses to a few questions about their intentions, past behavior, and present behavior. The algorithms assess individual readiness to take action, such as to quit smoking or to exercise regularly for 30 minutes a day. The response categories place participants in one of five stages: Precontemplation (not intending to take an action such as quitting smoking in the next six months), Contemplation (intending to take action in the next six months), Preparation (intending to take action in the next 30 days), Action (already quit smoking but for less than six months), or Maintenance (quit smoking for more than six months).

Decisional Balance

Change requires the consideration of the potential gains (Pros) and losses (Cons) associated with taking action. The Decisional Balance Inventory consists of two scales, the Pros of Change and the Cons of Change. Longitudinal studies have found those measures to be among the best available predictors of future change.¹⁹ Across more than 50 behaviors, Hall and Rossi,²⁰ and Prochaska, Velicer, Rossi, et al.²¹ found that the balance of Pros and Cons was systematically related to stage of change. The Cons of changing to a health-promoting behavior outweighed the Pros in the Precontemplation stage; the Pros surpassed the Cons in the middle stages; and the Pros outweighed the Cons in the Action stage. So the first principle of helping patients progress in Precontemplation is to increase the Pros of changing. Ask a couch potato, “What are all the benefits that you could get from regular exercise?” They can usually list four or five. Tell them there are at least 40 scientifically-documented benefits (see the Appendix). Ask them to try to double their list, and they can start changing. Let them know that there is something they can do for 30 minutes a day that can give them so many benefits.

Participants in the Contemplation stage need to lessen the Cons of changing. For quitting smoking, withdrawal is one of the big Cons. Fortunately, there are a variety of medications, such as nicotine replacement therapies, that can dramatically reduce this Con.

Self-Efficacy

Self-efficacy, or the degree to which an individual believes he or she has the capacity to attain a desired goal, can influence motivation and persistence.²² Self-efficacy in the TTM has two components that are distinct but related: confidence to make and sustain changes, and temptation to relapse. Like decisional balance, levels of self-efficacy differ systematically across the stages of change, with subjects further along in the stages of change generally experiencing greater confidence and less temptation. Self-efficacy means having the confidence to practice the healthy behavior in a variety of difficult situations (e.g., when one is stressed, has an increased workload, or has conflicting demands).

One of the best ways to increase self-efficacy is to help the patient set realistic goals. Patients in Precontemplation will have little confidence that they can take effective action at this time. But they can have

much greater confidence that they can progress to Contemplation (e.g., doubling their list of Pros). Once they start progressing, they can break out of their demoralized or defensive place, experience some success, and increase their self-efficacy. Temptations can be reduced by using strategies to cope with difficult situations, such as taking deep breaths rather than smoking as a way to reduce stress.

Processes of Change

In a comparative analysis of 24 major systems of psychotherapy, Prochaska and DiClemente²³ distilled a set of 10 fundamental processes by which people change. These 10 processes describe the basic patterns of activity that should be encouraged by clinicians to help patients change problem behaviors:

Consciousness raising	Finding and learning new facts, ideas, and tips that support the healthy behavior change
Dramatic relief	Experiencing the negative emotions (fear, anxiety, worry) that go along with unhealthy behavior risks
Self re-evaluation	Realizing that the behavior change is an important part of one’s identity as a person
Environmental re-evaluation	Realizing the negative impact of the unhealthy behavior or the positive impact of the healthy behavior on one’s proximal social and physical environment
Self-liberation	Making a firm commitment to change
Helping relationships	Seeking and using social support for the healthy behavior change
Counter-conditioning	Substituting healthier alternative behaviors and cognitions for the unhealthy behaviors

Reinforcement management	Increasing the rewards for the positive behavior change and decreasing the rewards of the unhealthy behavior
Stimulus control	Removing reminders or cues to engage in the unhealthy behavior and adding cues or reminders to engage in the healthy behavior
Social liberation	Realizing that the social norms are changing in the direction of supporting the healthy behavior change.

Figure 36.4 depicts our current understanding of the patterns of emphasizing particular processes as they progress through the stages.²⁴

Figure 36.4 Stages of change in which particular processes of change are emphasized

Stage-Matched Interventions Based on the TTM

In addition to providing an assessment framework, the TTM provides a scheme for tailoring programs by matching them to the needs of patients at each stage of change for a new healthy behavior. The degree of tailoring possible depends directly on the extent of the assessment. The following are descriptions of how one could use TTM for increasing a healthy behavior through manuals, provider interventions, or internet-based programs.

Stage-Based Manuals

When only the staging algorithm is administered, tailoring can occur at the stage level. Stage-based manuals describe how self-changers progress through each stage of change, and how they recycle if they relapse. The manuals teach users about general principles of

behavior change, about their particular stage of change, and the processes they can use to progress to the next stage. Appropriate sections of the manuals are matched to each stage of change and provide detail on change processes and stage-matched exercises. There are several ways to use the manuals. First, they can be read for the big picture of how people change; next, readers can turn to the section for the stage they are in and study that stage for a while. This is a good way to be sure they are heading in the right direction. Then, users can look ahead to the next stage to learn more about how to move forward. For example, if a patient in the Precontemplation stage for effective stress management is underestimating the Pros, that patient could use the section of the manual that describes dozens of documented Pros of doing effective stress management. The patient would also be encouraged to seek more information about the importance of stress management from the media and their healthcare provider.

*Changing for Good*²⁵ is a popular paperback that patients can use to help guide them through the stages of change for a broad range of health behaviors and other problem behaviors. Or a stage-based manual specific to stress management, smoking cessation, medication adherence, exercising regularly, or weight management can be viewed at www.prochange.com.

Stage-Based Provider Guidance

Healthcare providers can also tailor interventions to the patient's stage of change by administering the staging algorithm (e.g., in the waiting room). Providers can then base brief interventions on processes that are most helpful to a particular stage. For example, Precontemplators come in denying or minimizing their problems. They may be unaware of the negative consequences of their unhealthy behavior or they may be demoralized because of repeated failures in changing their behavior.

The goal for the provider is to engage **Precontemplators** in the change process. Lecture and confrontation won't work. Trying to pressure or persuade them to take immediate action will only make them more defensive or demoralized. As we saw earlier, just helping them to increase their awareness of the Pros of changing will help them to progress. Providers also can help Precontemplators raise consciousness by teaching them about the stages of change, and providing more information to dispel any misconceptions the patient may have. During the first appointment with Precontemplators, providers

can ask if they are willing to do any of the following before the next time they meet:

- Read about the healthy behavior
- Double their list of the Pros
- Talk with someone who has successfully changed the target behavior.

Providers should reinforce the notion that their patients *have* the capacity to progress (see related discussion in the first part of this chapter). They should remind their patients that any forward movement (e.g., becoming more open to considering alternatives, becoming more aware) is progress; change does not equal action—change means progressing to the Contemplation stage.

Contemplators are thinking about changing but are not yet committed to do so. They are more likely to acknowledge that their behavior needs to be changed, but they substitute thinking about it for acting on it. They recognize the benefits of changing, but overestimate the Cons. Contemplators are ambivalent about changing and are often waiting for the magic moment. Providers can assist by acknowledging the ambivalence and working to resolve it by encouraging Contemplators to weigh the Pros against the Cons. Patients are asked to shrink Cons by comparing them to the growing list of Pros, by asking how important they are relative to the Pros, and by challenging themselves to counter the Cons. For example, time is the number one Con for regular exercise. But time becomes less of a barrier if we can get more than 40 benefits for 30 minutes. Interventions in these appointments can be more ambitious, including taking small steps toward the healthy behavior. For example, smokers in Contemplation can be given three choices to progress to Preparation:

1. Quit for 24 hours in the next month;
2. Delay the first cigarette by an extra 30 minutes; or
3. Reduce the number of cigarettes they smoke by three or four.

“Which are you most confident you can do? Great. Take it and run with it.”

Providers can help by using motivational interviewing strategies like reflective listening to assist Contemplators to resolve their ambivalence by working with them to identify the negative consequences of continuing the unhealthy behavior, and by providing case examples of people who have been able to change.

Helping patients create a healthier image is important in Contemplation. Providers can encourage patients to ask themselves about their image. For example, “How do you think and feel about yourself as an inactive person? What might it be like if you became more active?”

Patients in Preparation assess the Pros as more important than the Cons, are more confident and less tempted, are developing a plan, and are more likely to participate in programs. With those in Preparation, providers need to be experienced coaches to provide encouragement. They need to coach, not lecture, and give praise, support, and recognition for taking small steps; keep interventions short, focused, and action-oriented; be available for phone support; focus on developing a plan for doing the healthy behavior; and problem solve.

Providers can enhance progress by ensuring that patients choose steps that are realistic, concrete, and measurable. Those in Preparation should be asked to put plans in writing and to role play how they will tell others about their commitment to their healthy behavior. It is important to help patients identify sources of support for their new behaviors—family members, co-workers, or friends. Providers can also help the patient to think about how they will feel about themselves after they have started making changes.

Patients in Action have recently begun doing the healthy behavior. They are using behavioral processes of change. Their confidence is building, but temptation and risk of relapse are concerns. Providers with patients in Action need to be facilitators for the behavior change. The focus is on the behavioral processes of change—counter-conditioning, stimulus control, and reinforcement management. It is also important to help patients plan ahead to prevent lapses and relapses.

Providers can help by getting patients to identify problematic beliefs and behaviors that inhibit change, and then by problem solving about positive alternatives that they believe will work for them. People, places, and things that increase the likelihood of not adhering need to be avoided or controlled (tempting cues). Reminders in both familiar and unexpected places that support the healthy behavior need to be left around—like a gym bag filled and ready to use, a picture on the desk of relaxing with friends, or pill-taking scheduled on the calendar. Those in Action also need to notice the intrinsic rewards of their healthy behavior—better health, more energy, more control of life. Patients need to reward themselves with positive state-

ments; providers can praise achievements and help patients recognize the benefits of their efforts.

Here is a simple strategy that can help patients activate a series of important change processes. “Do you make to-do lists? OK, good. Now, for this week, write in your to-do list *walking for my heart*. Next week, *walking for my stress*. Then, *walking for my bones*; *walking for my brain*; *walking for my immune system*. Pretty soon you will be running.” This technique involves self-liberation (writing down a commitment to walk); stimulus control (continue walking); and reinforcement (scratching walking off one’s daily to-do list). This approach helps providers communicate to their patients that they care for them as whole people and not just as patients with a disease. Patients are being encouraged to walk not only to prevent or manage a disease like diabetes or CVD; they are encouraged to walk to enhance the health of their whole self—body, mind, and spirit.

Patients in Maintenance have high confidence, and temptations are low. They are at risk primarily in times of distress or atypical temptations. With those in Maintenance, the provider needs to be a consultant to provide advice regarding relapse prevention. Providers can do this by helping patients to cope with distress (the major cause of relapse), continuing to refine a relapse prevention plan, being available to provide support, and establishing a support system in the community. For many people, Maintenance can be a lifelong struggle—it is a dynamic not a static stage. There needs to be work to consolidate gains and increase self-efficacy through increasing coping skills.

Remember, a majority of individuals relapse to earlier stages before reaching permanent Maintenance. Your job is to make sure they don’t give up on themselves and that you don’t give up on them.

Intra- and Internet Expert System Program

Lengthier assessments that include each of the constructs of the TTM permit significantly more tailoring, but may be impractical in a clinic setting where competing demands limit time. We have developed computerized tailored health behavior change programs that are designed to be easy and engaging for patients to use and can be delivered over intra- or internet platforms which offer a cost-effective, easily disseminated alternative. The technical basis for these systems relies on the integration of statistical, word processing, multimedia, and database software. A system resides either on an internet server or

a local network server, and can be accessed by anyone who has the appropriate address and password. Such programs are being made more available to patients through their insurers or employers. Once a patient logs onto the program, they are asked to complete a TTM assessment that evaluates stage, decisional balance, self-efficacy, and the processes of change.

During a patient’s first use of the program, feedback is based on a comparison of the responses of the individual to a larger comparative sample of successful and unsuccessful individuals making the behavior change. This feedback relies only on normative comparisons, which differ by stages. The initial norms are derived from a naturalistic sample of individuals. Evaluation of the expert system provides updated norms at periodic intervals. The second and subsequent interactions compare the individual to both the normative group and to their own previous responses, and provide both ipsative (i.e., self-comparisons) and normative comparisons. The ipsative comparisons require access to the database for the results of the previous contact. The program makes individualized recommendations of change and guides the participant through the behavior change process that meets their individual needs.

The computer generated feedback also links or refers participants to sections of a stage-matched self-help interactive resource workbook. Like the stage-matched manual described above, the online integrated workbook teaches users about general principles of behavior change, as well as their particular stage of change and the processes they can use to progress to the next stage. The individualized feedback reports refer participants (via links) to appropriate sections of the workbook to provide more detail on change processes and stage-matched exercises. For example, a participant can link to the online workbook where there are testimonials about the effects of stress from people who are now effectively managing their stress, an exercise to learn about what controls one’s behavior, a bulletin board listing rewards people give themselves for effectively managing stress, and substitutes for unhealthy stress management that don’t involve food, smoking, or alcohol. For a sample of this program designed for stress management, please go to www.prochange.com/PDF/stress.pdf.

Summary

What is the number one reason that a majority of providers do not practice behavioral medicine? Time is number two. Reimbursement is number three. The number one reason is that two-thirds of providers have come to believe their patients cannot change or will not change. We are convinced they have become demoralized by the action paradigm.

Here is a prescription for producing a demoralized provider and a non-compliant patient. An actual case involved a 50-year-old obese male recently diagnosed with type 2 diabetes. His physician with all good intent told him, "You have to test your blood glucose twice a day, take your medication twice a day, change your diet, exercise, quit smoking, and lower your stress. Good luck!"

Two large population studies demonstrated that health behavior changes could be made simultaneously with populations of patients with diabetes by applying counseling, computers, and manuals.^{26,27} But the patients were not asked to take action on these behaviors at once. Less than 10% were ready to take action on two or more of those risks. They were helped to set goals that were realistic for the stage they were in and then to use principles and processes of change to progress from one stage to the next.

As professionals, we can apply the same approach to changing our own behaviors. The goal for this chapter was to help you progress one stage toward adopting a more effective approach to functional medicine. If you have progressed just a single stage, then our time together has been worthwhile.

Metabolic Syndrome, Cardiovascular Disease, and Related Conditions: Extended Discussion

Mark C. Houston, MD, MSc, SCH, ABAAM, FACP, FAHA

Fifty-five (55) year-old white male, long-distance truck driver, presents with a chief complaint of “headache, chest pain, and shortness of breath with exercise.” (Table 37.1 provides a list of abbreviations used this chapter.)

Present Illness

The patient states that he began to have occipital headaches three months prior to this visit. The headaches were described as a dull ache, intermittent, but worse early in the morning and often would wake him up. The headaches were five out of ten in severity, without radiation or other associated symptoms initially, and were relieved partially by aspirin or acetaminophen. About two months prior to his visit, he had one episode of numbness and weakness in his right hand, associated with mild dizziness and posterior headache while driving his truck; it lasted for less than five minutes, resolved completely, and has not recurred since. One month ago, he noticed substernal chest pain and dyspnea while unloading his truck and also when walking up steps in his home. The chest pain was described as a “heaviness and aching” in the middle of the chest with some radiation into the left arm and hand, eight out of ten in severity and relieved by resting for three to four minutes. He also noted some shortness of breath and mild wheezing with the exertional chest pain that was so severe that he had to stop and rest. There was no cough,

hemoptysis, or sputum production. He denied any other symptoms or problems.

Personal History

Social: He was born in southern Georgia where he has lived all of his life. He is married and has four children, ages 16, 20, 23, and 25. His wife recently lost her job, has been very depressed, and has started drinking alcohol heavily. They have had financial problems since then, and he has taken out a loan from the bank. He is contemplating working extra shifts for the trucking firm to pay back the loan and improve his finances. His youngest son has been arrested twice for DUI and is failing his high school classes. The patient started working as a long-distance truck driver 37 years ago, when he dropped out of high school early to support his mother after his father died of a heart attack at the age of 43. All members of his extended family moved to Texas 10 years ago and he rarely sees them or communicates with them. His wife’s family lives in Mississippi, and they do not see them much either.

Habits, nutrition and exercise: The patient has smoked two packs of cigarettes per day for 40 years, drinks six beers per day, and consumes 10 to 12 cups of coffee and six soft drinks per day. He has less than one glass of tap water per day. He eats mostly in fast food restaurants with lots of “burgers, fries, fried chicken, tacos, and burritos.” He hates fruits and vegetables

Table 37.1 Abbreviations Used in Chapter 37

A-II	Angiotensin-II	IVUS	Intravascular coronary ultrasound
ABP	Ambulatory blood pressure	LAD	Left anterior descending
ACEI	Angiotensin-converting enzyme inhibitor	LAH	Left atrial hypertrophy
ARB	Angiotensin-receptor blocker	LCX	Left circumflex
BMI	Body mass index	LDL	Low density lipoprotein
C ₃	Complement 3	LP (a)	Lipoprotein (a)
CCB	Calcium channel blocker	LVH	Left ventricular hypertrophy
CHD	Coronary heart disease	MAPK	Mitogenactivated protein kinase
CSF-1	Colony stimulating factor-1	MAU	Microalbuminuria
CVD	Cardiovascular disease	MCP-1	Monocyte chemoattractant protein-1
DBP	Diastolic blood pressure	MI	Myocardial infarction
EBT	Electron beam tomography	MIP-1 α	Macrophage inflammatory protein-1 alpha
eNOS	Endothelial nitric oxide synthase	MUFA	Monounsaturated fats
FBG	Fasting blood glucose	NMR	Nuclear magnetic resonance analysis
FBS	Fasting blood sugar	OGTT	Oral glucose test
FFA	Free fatty acids	PAI-1	Plasminogen activator inhibitor-1
GFR	Glomerular filtration rate	PGE	Prostaglandin E
HCT	Hematocrit	PI3-K	Phosphatidyl inositol 3 kinase
HDL	High density lipoprotein	PPAR	Peroxisome proliferator activated receptors
HS-CRP	High sensitivity C-reactive protein	PRA	Panel-reactive antibody
IBW	Ideal body weight	PUFA	Polyunsaturated fats
ICAM	Intracellular cell adhesion molecule	ROS	Reactive oxygen species
IL-6	Interleukin-6	SBP	Systolic blood pressure
ILI-B	Interleukin 1B	TG	Triglyceride
IMT	Intimal medial thickness	TNF- α	Tumor necrosis factor-alpha
IR	Insulin resistance	VLDL	Very-low-density lipoprotein
IRS 1/2	Insulin receptor substrate 1 and 2	VSM	Vascular smooth muscle

other than potatoes, and often eats steak and mashed potatoes when he is home. His usual breakfast is a cup of coffee, a Danish, and a cigarette. He carries various types of candies and sweets in his truck to snack on during the day. He is in his truck either driving or sleeping 70% of the time. He uses the air conditioner or heater in the truck depending on the weather, but never has the windows open. The only exercise that he gets is when he occasionally unloads a few boxes from his truck. He states that he has been overweight since he was 21 and has gained over 30 pounds in the last 10 years. His work schedule allows little time for socializing with family and friends and he is so “stressed out” and “depressed” about his job, finances, wife, and son that he wants to be alone most of the time anyway. He has never attended any religious services or church.

Past Medical History

Hospitalizations and operations: None

Medical illnesses: Mild sinus congestion and “heartburn”

Infectious diseases: Mumps, rubella, and chickenpox as a child; otherwise, negative

Immunizations: Tetanus toxoid six years ago

Skin tests: N-isopropyl-N'-phenyl-p-phenylenediamine (IPPD) is negative

Injuries: None

Transfusions: None

Medications: Aspirin (four to five per day), acetaminophen (four per day), TUMS® (six per day) and prn over-the-counter sinus medications.

Allergies: None

Family history: Father died at 43 of a heart attack. He had hypertension and high cholesterol, smoked heavily, and was obese. Mother is alive at 83 with osteoarthritis, hypothyroidism, and hypertension. Brother is 57 and had a heart attack at age 50. He is also hypertensive and has high cholesterol. He now has severe congestive heart failure and is on disability. Sister is 49 with hypertension and high cholesterol. Grandfather died at 56 of unknown causes. Grandmother died at 71 of unknown causes.

Review of systems: Negative except for those symptoms and problems mentioned in the present illness.

Physical Exam

General: Obese, anxious, pleasant white male appearing older than his stated age.

Blood pressure: First blood pressure was 182/104 mm Hg in left arm sitting. Five minutes later the blood pressure was 176/102 mm Hg in the left arm sitting. Ten minutes later the blood pressure was 178/104 mm Hg in the right arm sitting. Twelve minutes later the blood pressure was 170/100 mm Hg in the left arm standing.

Heart rate: The initial heart rate was 92 and regular while sitting. Five minutes later the heart rate was 90 and regular while sitting. Ten minutes later the heart rate was 80 while sitting. Twelve minutes later the heart rate was 82 and regular while standing.

Temperature: 98.8° F

Respiratory rate: 16 and non-labored

Weight: 225 pounds, large frame

Height: 5 feet, 10 inches

Waist circumference: 42 inches (normal <40)

Waist-hip ratio: 1.4 (normal <1.0)

Body mass index (BMI): 32.0 kg/m². Stage 1 obesity (normal is <25). BMI is weight in kg divided by m² in height.

Percent body fat: 28% (normal <16% in males)

Skin: No rash, abnormal nevi, or other lesions; normal hair and nail examination.

Head and neck: Eyes show no scleral icterus; mild erythematous scleral injection bilaterally; extraocular motion intact; and normal visual fields. Pupils are equal and reactive to light and accommodation. Vision is 20/20 bilaterally. Retina shows grade 2 Keith-Wagener hypertensive changes with arteriolar narrowing and arteriolar/venous nicking. Optic discs appear normal. Ears have normal hearing with no abnormalities. Nose and mouth are erythematous without lesions. Neck shows bilateral carotid bruits, supple, no thyromegaly, neck masses, or lymphadenopathy.

Chest: Mild barrel chest; hyper-resonant to percussion; diffuse expiratory wheezes, no rales or rhonchi; no chest wall tenderness.

Cardiac: Regular rate and rhythm; increased intensity of the second heart sound, A-2 with an S4 atrial gallop sound and a II-III/VI holosystolic murmur at the lower left sternal border, but loudest at the apex with radiation to this area.

Pulses: Normal pulses in the radial, brachial, femoral, posterior tibial and dorsalis pedis bilaterally; minimal diminution of the carotid pulses bilaterally.

Abdomen: Obese, soft; normal bowel sounds; minimal tenderness in the mild epigastric area; no palpable liver, spleen or other masses; no abdominal or renal bruits.

Lymphatics: No lymph node enlargement in the cervical area, axillary, epitrochlear, inguinal or any other location.

Musculoskeletal: Normal muscle strength, tone, and flexibility.

Neurological: Mildly depressed and anxious affect; normal short- and long-term memory; normal cranial nerves; normal motor and sensory examination with normal reflexes in the upper and lower extremities bilaterally.

Genitourinary: Both testicles descended without masses or tenderness and no scrotal masses.

Rectal: Stool negative for occult blood; prostate two plus enlarged without masses or tenderness.

Extremities: No cyanosis, clubbing or edema

Nutritional Evaluation (done with diet diary and nutritionist interview)

Total daily caloric intake: 3600 KCAL

Macronutrient percentages:

Simple and refined carbohydrates: 60%

Crude fiber: <5 grams

Protein: 15%

Fats: 25%

Saturated fats: 82%

Polyunsaturated fats (PUFA): 5%

Monounsaturated fats (MUFA): 5%

Trans fats: 8%

Exercise

Total estimated aerobic exercise per day: 10 minutes

Resistance: No resistance exercise except for occasional lifting of boxes from his truck

Initial Lab Results

Initial visit tests for urinalysis, urea nitrogen, sodium, potassium, chloride, carbon dioxide, calcium, total protein, albumin, globulin, total bilirubin, alkaline phosphatase, AST, ALT, T₄, FT₄, FT₃, TSH, prostate specific antigen, 24-hour urine volume, and total cholesterol

Section VII

Putting It All Together

were within normal limits. Urine, serum, hair, and nail evaluations were performed for mercury, lead, arsenic, cadmium, etc. and were normal. The following tests were abnormal:

Sed rate by modified Westergren 42 mm/hr
(normal ≤ 20)

Creatinine, 24-hour urine 2.69 g (normal range
0.63–2.50 g)

Iron binding saturation 52% (normal range
10–36%)

Cardiovascular Testing

24-hour ambulatory blood pressure monitor:

Increased BP load and mean BP

Systolic blood pressure (SBP): >140 mm Hg, 95%
(normal load is <15%)

Diastolic blood pressure (DBP): >90 mm Hg, 88%
(normal load is <15%)

Mean BP: 178/98 mm Hg

No nocturnal dipping (normal decrease is SBP
10%–12% and decreased DBP 14%–17%)

Treadmill test: Positive hypertensive response to exercise, 220/112 mm Hg, with 1½ mm ST segment depression in the inferior, anterior, and lateral leads with T-wave inversion

Thallium treadmill test: Positive—anterior, inferior, and lateral perfusion defects/ischemia

Carotid artery duplex: Increased intimal medial thickness (IMT) with 60% left common carotid artery obstruction and 40% right common carotid artery obstruction

Electron beam tomography (EBT): Multi-site Ca++ – inferior, anterior, lateral. Calcium score (CAC): 485 (>99th percentile) (Figure 37.1)

Computerized arterial pulse wave analysis (age and gender adjusted):

C-1 AC: 8, which is low (normal is >12)
(large arterial compliance)

C-2 AC: 2, which is low (normal is >7) (small
arterial compliance)

Cardiac echo: Mitral regurgitation 1+ to 2+, moderate left ventricular hypertrophy (LVH), diastolic dysfunction, enlarged left atrium (LAH)

Electrocardiogram (EKG): Abnormal—sinus tachycardia, non-specific diffuse ST-T wave changes, LAH and LVH

Chest x-ray: Abnormal—hyperexpanded lung fields consistent with early emphysema; increased interstitial markings in the bases of both lungs

Renal artery duplex: Normal

Coronary arteriogram: Normal coronary arteries; no obstructive disease

Intravascular coronary ultrasound (IVUS): Severe extra-luminal atherosclerotic disease in left anterior descending (LAD), left circumflex (LCX), and right coronary arteries (Figure 37.2 shows an image that is very similar to this patient's).

Standard Diagnostic Summary

Cardiovascular

Disease manifestations:

1. Hypertension: Essential/genetic/nutritional, obesity and lifestyle. High plasma renin activity (PRA), high catecholamines and cortisol. Stage 2
2. Dyslipidemia: Familial/nutritional/lifestyle. Low HDL-C, increased LDL particle number, dense/small LDL, dense/small HDL, intermediate very-low-density-lipoprotein (VLDL), elevated lipoprotein a [LP(a)] (Figure 37.3 shows an NMR lipoprotein analysis)
3. CHD: Non-obstructive, symptomatic, positive EBT, microvascular ischemia
4. Generalized endothelial dysfunction and reduced arterial compliance
5. Bilateral carotid artery disease/obstruction and increased IMT
6. Mitral regurgitation: moderate
7. LVH and left atrial hypertrophy (LAH)
8. Diastolic dysfunction
9. Resting tachycardia
10. Chest pain secondary to hypertension, LVH and microvascular angina
11. Carotid artery obstruction with history of transient ischemic attacks

Risk factors and contributing factors:

12. Homocysteinemia
13. Elevated hs-CRP (high-sensitivity C-reactive protein) and ESR (erythrocyte sedimentation rate)
14. Polycythemia
15. Elevated iron, iron stores, and percent saturation
16. Elevated fibrinogen

Renal

17. Mild renal insufficiency with MUA

Hematology

18. Leukocytosis

Endocrine

19. Obesity: Stage I—high risk
20. Insulin resistance/metabolic syndrome: Hypertension, android/central obesity (BMI, waist circumference, waist-hip ratio); increased hs-CRP; increased

adipose tissue as a percentage of body weight; elevated fasting blood sugar (FBS) and 2 hour oral glucose test (OGTT), C-peptide, Hg A₁C, and insulin with impaired glucose tolerance, dyslipidemia

Gastrointestinal

21. Gastritis/Gastroesophageal reflux disease (GERD)

ENT

22. Sinusitis
23. Headaches secondary to hypertension and/or sinusitis

Pulmonary

24. Dyspnea secondary to lung disease
25. Emphysema and chronic obstructive pulmonary disease secondary to tobacco abuse

Nutritional Problems

26. Multiple micronutrient and macronutrient deficiencies
27. Reduced antioxidant defenses with increased oxidative stress
28. Caffeine abuse
29. Soft drink abuse

Genetics

30. Positive family history of premature CHD, hypertension, hyperlipidemia

Psychosocial

31. Stress, anxiety, and depression

Functional Medicine Assessment: Using the Matrix

The functional medicine matrix (presented in Chapter 34) can help to organize the multiple inter-connected elements of this patient's primary disease, the metabolic syndrome. Pathophysiology, nutrition, biochemistry, prevention, and treatment will be discussed utilizing a functional medicine approach. Following the conclusion of the Case Presentation, an extended discussion of metabolic syndrome can be found.

LIPOPROTEIN PANEL

		Coronary Heart Disease (CHD) Risk Categories				
LDL Particle Number	nmol/L	Optimal*	Near or above optimal	Borderline-High	High	Very high
	1809	under 1100	1100 - 1399	1400 - 1799	1800 - 2100	over 2100
*Goal for patients with CHD or CHD risk equivalents						
LDL Size	nm	Pattern A (large LDL)		Pattern B (small LDL)		
	19.2	22.0 - 20.6		20.5 - 19.0		
		Lower-Risk		Higher-Risk		
Large HDL (cholesterol)	mg/dL	Negative Risk Factor		Intermediate	Positive Risk Factor	
	3	greater than 30		30 -11	less than 11	
Large VLDL (triglyceride)	mg/dL	Lower-Risk		Intermediate	Higher-Risk	
	12	less than 7		7 - 27	greater than 27	

RISK ASSESSMENT PANEL

Elevated LDL Particle Number >1400 nmol/L ☒

Lipoprotein Traits of the Metabolic Syndrome* ≥2 traits ☒

Lipoprotein Traits of the Metabolic Syndrome*

Small LDL Pattern B (≤ 20.5nm) ☒

Reduced Large HDL (<11 mg/dL) ☒

Elevated Large VLDL (>27 mg/dL) ☐

*Elevated numbers of LDL particles and the lipoprotein traits of the metabolic syndrome affect CHD risk interactivity. Risk is highest when both are present.

Figure 37.3 NMR lipoprotein analysis

Environmental Inputs: The Influence of Environment on Gene Expression

Diet: His caloric intake is excessive with incorrect proportions of macronutrients. Excessive calories and obesity contribute to vascular inflammation, endothelial dysfunction, vascular and cardiac structural abnormalities, oxidative stress, and hormonal imbalance.^{1,2,3,4,5} These, in turn, contribute to his metabolic syndrome, insulin resistance, dyslipidemia, hypertension, and many other problems.^{6,7,8,9,10} Adipose tissue is both the source and target of inflammatory mediators.^{11,12}

Nutrition: His refined carbohydrate content is too high; crude fiber content is too low; the protein types and proportions are inappropriate; saturated and *trans* fats are disproportionately represented, with suboptimal intake of PUFA and MUFA. There is inadequate consumption of fruits and vegetables, low-fat dairy, and many micronutrients. His poor nutritional status is a major contributing factor for vascular inflammatory biology, immune dysfunction, oxidative stress with reduced oxidative defenses, mitochondrial dysfunction, hormonal imbalance, vascular structural abnormalities, and endothelial dysfunction.^{13,14,15,16,17,18} These are the basic underlying pathophysiological abnormalities, for his most pressing health problems (obesity, metabolic syndrome, insulin resistance, dyslipidemia, hypertension, CHD, and vascular disease). His nutritional state creates an inflammatory, oxidatively stressed, immunologically and hormonally imbalanced environment.

Air and water: He gets little fresh air, with ventilation primarily from air conditioning and heat from his truck. He is chronically dehydrated due to excess caffeine and sodas (diuretic effects) combined with insufficient water intake. This will affect his body's ability to provide adequate hepatic metabolism, detoxification, and renal excretion of xenobiotics.

Physical exercise: He has minimal-to-no aerobic or resistance exercise and lives a very sedentary lifestyle. Exercise improves insulin resistance, vascular inflammation, vascular endothelial function and vascular structure, increases lean muscle mass, reduces adiposity, improves gastrointestinal function, hormonal balance, oxidative stress, and immune function.^{19,20,21,22,23,24,25,26,27,28,29,30,31} The lack of exercise contributes to his insulin resistance, metabolic syndrome, CHD, dyslipidemia, and hypertension, as well as other health issues.

Xenobiotics: The excessive intake of aspirin and TUMS could be causing his gastric and renal problems.^{32,33} The excessive TUMS (calcium carbonate) may alter blood pH, increase serum calcium, reduce phosphorous, and cause rebound gastric acidity.³⁴ Acetaminophen will deplete glutathione, impair hepatic metabolism, detoxification and biotransformational processes of drugs, xenobiotics and nutrients, as well as inducing hepatic and renal dysfunction.³⁵ The glutathione deficiency contributes to reduced oxidative defense and increases vascular inflammation and the risk for CHD and MI.^{36,37}

Radiation: No obvious exposure.

Psychosocial: He has major psychosocial problems (as noted in the history) that are contributing to his health by inducing hormonal imbalances, oxidative stress, endothelial dysfunction, immune dysfunction, and inflammation, all of which contribute to his hypertension, hyperglycemia, dyslipidemia, and CHD.^{38,39,40,41,42,43,44,45,46} The significant problem areas are:

- Family
- Work
- Community
- Economic status
- Stress
- Lack of support

Emotional, mind, and spirit: His life of anxiety, depression, and chronic stress creates hypercortisolism, a hypercatecholamine state, oxidative stress, and suppressed immune function, contributing to hyperglycemia, hypertension, dyslipidemia, endothelial function, and vascular disease.^{47,48,49,50,51,52,53,54,55}

Hormonal and Neurotransmitter Messenger Imbalances

The patient exhibits excessive production of cortisol, catecholamines, and insulin. Each of these hormones in excess will induce inflammation, oxidative stress, and structural abnormalities, and will interfere with various biochemical and nutritional pathways that are related to his hypertension, hyperglycemia and diabetes, dyslipidemia, vascular disease, and other problems.^{56,57,58,59,60,61,62,63,64,65,66,67,68}

Oxidation-Reduction Imbalances and Mitochondriopathy

The mitochondria are intimately involved in insulin resistance and the metabolic syndrome.^{69,70,71,72,73,74} The mitochondria are smaller, have impaired bioenergetic capacity with a defect in oxidative phosphorylation and production of adenosine triphosphate (ATP).^{75,76,77} The skeletal muscle has a marked increase in the intramyocellular lipid content. The insulin resistance results in preferential metabolism of FFAs with reduced glucose utilization. The FFAs inhibit glucose uptake transporter-4 and enhance gluconeogenesis. Adipose tissue releases specific cytokines such as TNF-α and IL-6, which increase inflammation, hs-CRP, exacerbate the insulin resistance and increase FFA concentration.^{78,79} TNF-α also inhibits endothelial nitric oxide (eNOS) and NO, elevating blood pressure. The FFAs increase uncoupling protein 3, which uncouples mitochondrial respiration from oxidative phosphorylation and increases oxidative stress and release of superoxide anion and subsequent ROS.^{80,81,82,83,84,85,86,87,88} A genetic polymorphism, called PGC-1 (PPAR gamma coactive-1) regulates mitochondrial biogenesis and fat oxidation

and is essential for the synthesis of the mitochondrial enzymes for the beta-oxidation of fatty acids.⁸⁹ PGC-1 levels are increased by weight loss, exercise, and optimal nutrition.^{90,91,92}

Detoxification and Biotransformational Imbalances

The various micronutrient deficiencies noted in the antioxidant panel analysis (described at the bottom of Table 37.2, which shows the patient’s lab results over 12 months) will contribute to a wide variety of abnormalities in hepatic detoxification of intrinsic toxins and xenobiotics by the cytochrome P450 system as well as other pathways.⁹³ In addition, many biochemical nutritional pathways will be impaired by deficiencies in B vitamins, amino acids, carnitine, vitamin D, calcium, zinc, magnesium, glutathione, CoQ10, vitamin E, and lipoic acid that will have enormous downstream effects on inflammation, immune function, hormonal and neurotransmitter function, oxidative stress, and vascular functional and structural integrity.⁹⁴ These will induce dyslipidemia, hypertension, and insulin resistance, among other problems.⁹⁵

Table 37.2 Patient Lab Results

General	Initial	2 Months	6 Months	12 Months
Magnesium	1.2 mg/dL	1.8 mg/dL	2.1 mg/dL	2.4 mg/dL
WBC/HCT	12,200/55	10,400/50	8,600/46	8,200/45
Creatinine	1.6 mg%	1.4 mg%	1.2 mg%	1.1 mg%
GFR	86 cc/minute	95 cc/minute	102 cc/minute	106 cc/minute
<i>Estimated GFR = (140 – age) x weight (Kg) / 72 x creatinine</i>				
24 hour urine MAU	80 mgs	22 mgs	0	0
Cortisol AM	30 mcg/dL	25 mcg/dL	18 mcg/dL	16 mcg/dL
Cortisol PM	22 mcg/dL	20 mcg/dL	12 mcg/dL	10 mcg/dL
PRA	9.2 ng/mL/hr	5.1 ng/mL/hr	1.2 ng/mL/hr	0.5 ng/mL/hr

Serum lipid peroxides	3.9 uM	2.8 uM	2.3 uM	2.1 uM
Urine lipid peroxides	2.4 uM	18 uM	14.9 uM	13.2 uM
Urine 8-OHdG	63 ng/mL	54 ng/mL	46 ng/mL	39 ng/mL
Total oxygen radical absorbance capacity (ORAC)	2200 uM	3000 uM	4200 uM	4400 uM
Other	Initial	2 Months	6 Months	12 Months
C-1 AC	8	14	16	17
C-2 AC	2	4	8	9

An antioxidant panel reviewing Vitamin E, B vitamins, amino acids, metabolites, fatty acids, Vitamin D, calcium, zinc, magnesium, glutathione, cysteine, selenium, and CoQ10 showed abnormal function initially (24th percentile), with steady improvements to the 50th (2 months), 70th (6 months), and 80th (12 months) percentiles for total antioxidant function.

Immune System and Inflammatory Messenger Imbalances

Adipose tissue is an active, intricate, metabolic paracrine and endocrine organ that produces a variety of “adipokines,” including inflammatory mediators and hormones that result in chronic inflammation, endocrine and metabolic dysfunction manifesting as insulin resistance, glucose intolerance, diabetes mellitus, dyslipidemia, hypertension, and vascular diseases such as CHD, MI, and carotid artery obstruction.^{96,97,98} The adipocytes are both a source and a target of proin-

flammatory signals, such as IL-6 and TNF- α .^{99,100,101} IL-6 and TNF- α increase hs-CRP, which is both a CVD risk marker and mediator of the inflammatory process and is highly correlated with future cardiovascular events.^{102,103} Adipose tissue—through its effective hormones, cytokines, and central nervous system mechanisms—regulates food intake, energy homeostasis, whole body insulin action and insulin sensitivity, body adiposity, carbohydrate and lipid metabolism, blood pressure, inflammation, thrombosis, and subsequent atherothrombotic disease.^{104,105}

Digestive, Absorptive, and Microbiological Imbalances

The presence of gastrointestinal pathology with mucosal inflammation and leaky gut may increase absorption of allergens, bacteria such as *Helicobacter pylori*, HIV, and various periodontal microorganisms that can contribute to vascular inflammation and oxidative stress-related CVD.^{106,107,108,109,110,111,112}

Structural Imbalances from Cellular Membrane Function to the Musculoskeletal System

Abnormalities in ionic membrane transport of sodium, potassium, magnesium, and calcium may result in increased intracellular content of calcium and sodium with reduced intracellular content of magnesium and potassium. These ionic concentration defects contribute to vascular and cardiac muscle dysfunction, hypertrophy and hyperplasia, reduced arterial compliance, insulin resistance, hyperglycemia, dyslipidemia, increased vascular resistance, hypertension, and subsequent CVD.^{113,114,115,116}

Goals of Treatment

General:

- Improve diet and nutrition.
- Improve physical fitness.
- Improve insulin sensitivity.
- Improve cardiovascular function.
- Improve antioxidant status.
- Reduce oxidative stress.
- Improve emotional status.

Specific:

Heart rate (resting): <70 beats per minute

Blood pressure:

- 110-120/70-75 mm Hg
- Blood pressure load <15 % of the SBP >140 mm Hg and DBP >90 mm Hg
- Re-establish normal nocturnal dipping

Dyslipidemia:

- LDL-C 60-70 mg%
- HDL >40 mg%
- TG <75 mg%
- LDL particle number <900 nmol/L
- LDL to pattern A (large)
- HDL to large pattern
- VLDL to small pattern
- LP(a) <50 mg/dl

Homocysteine: <9.0 umol/L (ideal <5.0)

hs-CRP: <0.6 mg/L

Fibrinogen: <400 mg/dL

Serum iron(Fe): <180 microgm/dL

Serum ferritin: <300 ng/mL

FBS: <90 mg% (ideal <75 mg%)

Hemoglobin A1C: <5%

2 hour OGTT: <120 mg%

C-peptide (fasting): <2 ng/mL

24 hour urine MAU: 0 (<30 mg/24 hour)

Creatinine: <1.2 mg%

Improve arterial compliance: C-1 >12.0 and C-2 >7.0

Reduce WBC: <10,000

Ideal body weight (IBW): 166 pounds

Waist circumference: <38 inches

Waist-hip ratio: <1.0

BMI: <25

Percent body fat: <16%

Hematocrit (HCT): <46%

Glomerular filtration rate (GFR): stabilize or improve

Stabilization or regression of CHD by EBT and IVUS

Reduce LVH, diastolic dysfunction, and mitral regurgitation

Improve pulmonary function

Stabilize and improve carotid artery disease

Treatment Strategies

Action steps:

- Stop tobacco.
- Stop caffeine, sodas, and alcohol.
- Reduce or stop use of regular aspirin, acetaminophen, and TUMS.
- Baby aspirin per day should be continued.
- Phlebotomy for increased iron (every eight weeks until iron is normal).
- Reduce to IBW: 1-to-2 pounds per week.
- Aerobic exercise for 60 minutes per day and resistance exercise for 20-30 minutes per day three to four times per week.
- Meditation, yoga, prayer.

Diet and nutrition:

- DASH-2 diet, Paleo diet, or Mediterranean diet: 1,750–2,000 calories per day
- 8-10 servings of fruits and vegetables per day
- 30%-40% protein (fish, lean meat, fowl)
- 40% carbohydrates (complex, fiber) and significantly reduce refined carbohydrates

Reduce fats to 30% of calories:
 Saturated fats <10%; MUFA (extra virgin olive oil),
 PUFA, and omega-3/6 should be ~90% of fats.
 Eliminate *trans* fats entirely.
 Omega-3/6 ratio—2:1 to 4:1
 Fiber: >40 grams per day
 Garlic: 1-2 cloves per day
 Celery: 2-4 pieces per day
 Sodium: 50-100 mmol per day
 Potassium: 60-100 meq per day
 Whey protein (hydrolyzed): 30 grams per day
 Probiotic capsules: 2 bid
Nutraceuticals/vitamins/antioxidants/minerals:
 Alpha lipoic acid (with biotin 2,000 micrograms):
 600 mg bid
 Calcium: 500 mg bid
 Co-enzyme Q10: 60 mg bid
 Folic acid: 1,200 micrograms per day
 Fruit, vegetable and dark berry concentrate extract
 L-carnitine: 1,000 mg bid
 Lycopene tomato extract: 5 mg bid
 Magnesium chelates: 400 mg bid
 High gamma/delta mixed tocopherols: 400 IU per day
 N-acetylcysteine: 1,000 mg bid
 Niacin (non-flush) (IHN): 1.5 grams bid
 Olive oil: 1 teaspoon bid
 Omega-3 fatty acids
 DHA: 1000 mg bid
 EPA: 500 mg bid
 Selenium: 200 micrograms per day
 Taurine: 1.5 grams bid
 Tocotrienols: 100 mg at bedtime
 Vitamin B complex: 1 bid
 Vitamin B12: 1,000 micrograms per day
 Vitamin B6: 100 mg bid
 Vitamin C: 250 mg bid
 Vitamin D: 400 IU bid
 Zinc: 25 mg per day

Case Discussion

Although this case is complex (involving many details about different assessments, re-assessments, and interventions), it exemplifies exceptionally well the impact of the interaction of genes and environment on inflammatory, immune, hormonal, oxidative stress, mitochondrial, and structural pathways in vascular pathophysiology. This patient came in with an identi-

able genetic predisposition to cardiovascular disease and insulin resistance (by family history). He might never have manifested those diseases had he chosen a lifestyle that reflected an understanding of his risks and how to minimize them. Even after many years of subjecting his genes to a very poor environment, however, we were able to help him reverse his disease and regain his health.

This patient refused pharmacologic treatment. He was motivated and compliant with a nutritional and lifestyle approach, which resulted in normalization of virtually all laboratory and clinical problems over 12 months of aggressive treatment. Tables 37.2 and 37.3 present, respectively, the laboratory results and the patient visit record over the course of a year's treatment.

Utilizing the matrix helps to organize and visualize all the interconnected biochemical and physiological mechanisms that contribute to the *beginnings* of the vascular disease process. As we saw, certain mechanisms (inflammation, oxidative stress, endocrine dysfunction) were represented over and over again around the matrix, helping us to recognize where the preponderance of evidence about this patient was to be found. From there, we focused on treatments that address those common underlying pathways, thus normalizing multiple systems—in this case, without drugs.

Early diagnosis, aggressive prevention, and treatment directed at the genesis of identified functional abnormalities are more logical, efficient, and effective than directing treatment modalities at the endpoints of the clinical disease—the symptoms. Virtually none of the treatments listed above were directed toward symptoms; they were focused on restoration and normalization of function. Recognition of the downstream pleiotropic effects of nutrient imbalances, insufficiencies (for a particular patient in a particular environment), and deficiencies on the disease-development process is crucial to redirecting therapeutic emphasis. The vascular system has a finite number of ways to respond to an infinite number of insults. Identification and treatment of these initial and basic common insults will become the future of treatment in vascular medicine.

Table 37.3 Patient Visit Record

	Initial	2 Months	6 Months	12 Months
Weight	225 pounds	215 pounds	182 pounds	170 pounds
Blood pressure	182/104 mm Hg 176/102 mm Hg 178/104 mm Hg 170/100 mm Hg	120/76 mm Hg 118/74 mm Hg 118/72 mm Hg	112/72 mm Hg 116/74 mm Hg	110/70 mm Hg 112/72 mm Hg
BP load and dipping	Abnormal	Normal	Normal	Normal
Heart rate	92 regular 90 regular 80 regular 82 regular	74/minute	66/minute	62/minute
Waist circumference	42 inches	40 inches	36 inches	34 inches
Waist-hip ratio	1.4	0.9	0.8	0.7
BMI	32.0 kg/m ²	31 kg/m ²	26 kg/m ²	24 kg/m ²
% Body fat	28%	22%	18%	14%

Extended Discussion: Metabolic Syndrome and Cardiovascular Disease

Background

The current and expanding epidemic of obesity and the metabolic (insulin resistance) syndrome has fueled an increase in cardiovascular disease (CVD). The metabolic syndrome is an insulin-resistant state characterized by visceral obesity, hypertension, dyslipidemia, glucose intolerance, and microalbuminuria (MAU). The cardiovascular risk and complications may follow obesity by 10 or more years. Thus, escalating rates of obesity predict further substantial increases in type 2 diabetes mellitus, coronary heart disease (CHD), myocardial infarction (MI), and total CVD that are likely to rapidly eclipse rates observed throughout the 20th century in the U.S.^{117,118} Environmental and lifestyle factors (inappropriate nutrition such as consumption of high-calorie foods and refined carbohydrates; reduced physical activity) as well as genetic considerations are major contributors to the metabolic syndrome and visceral obesity.^{119,120}

The overall prevalence of metabolic syndrome is 24% in adults, with a higher incidence in minorities, and metabolic syndrome progressively increases with age, rising from ~7% for adults in the third decade of life to nearly 45% for those over 60 years of age.¹²¹

Risk Factors and Associated Conditions

Definitive associations of CVD and metabolic syndrome include a marked increased risk in CHD, MI, stroke, and total mortality that is directly proportional to the number of components of the metabolic syndrome.^{122,123,124} The incident risk of CVD is greater than five-fold in subjects with four or more components, compared to those with only one component.¹²⁵ There clearly exists a continuum of risk, based on both severity of the risk factor itself and on combinations of risk factors. The metabolic syndrome and obesity are major public health and economic problems that require urgent and aggressive identification, prevention, and treatment with lifestyle modifications (nutrition, weight reduction, exercise) and pharmacologic modalities.

Definitions

The term metabolic syndrome denotes a constellation of cardiovascular risk factors related to insulin resistance and obesity with a centripetal fat pattern. Definitions have varied, but the basic elements are well validated.^{126,127,128,129} National Cholesterol Education Program—Adult Treatment Panel III (NCEP-ATP-III) (2001)¹³⁰ and World Health Organization (WHO) guidelines (1999)^{131,132} include hypertension, atherogenic dyslipidemia (high triglyceride, low HDL, dense LDL), obesity (elevated waist circumference, BMI, waist-hip ratio), hyperglycemia, and MAU. (See Table 37.4.) However, this definition must be expanded to recognize the underlying mechanisms: insulin resistance, inflammation, and immunologic dysfunction with increased oxidative stress, prothrombotic components, vascular endothelial dysfunction, vascular structural abnormalities, and accelerated atheroembolic

disease.^{133,134,135} (See Table 37.5.) Insulin resistance is the primary underlying dysfunction. The metabolic syndrome with insulin resistance and inflammation precede clinical events by decades; thus, early detection is mandatory.

Mechanisms of Action

Imbalanced vascular endothelial mediators create endothelial dysfunction and inflammation, the earliest markers of atherosclerosis. Hypertension and atherosclerosis are primarily diseases of inflammation.¹³⁶ Excess angiotensin-II (A-II) and a deficiency of nitric oxide (NO) result in vasoconstriction, growth promotion, and a prothrombotic, proinflammatory, and prooxidant state. This constellation of events is directly connected to insulin resistance, the metabolic syndrome, and the frequent clinical association of hypertension, dyslipidemia, and diabetes mellitus.^{137,138,139,140,141}

Table 37.4 Published Criteria for the Diagnosis of Metabolic Syndrome

	National Cholesterol Education Program— Adult Treatment Panel III (NCEP-ATP-III)	World Health Organization (WHO)
Hypertension	Current antihypertensive therapy or BP >130/85 mm Hg	Current antihypertensive therapy and/or BP >140/90 mm Hg
Dyslipidemia	Plasma triglyceride level >150 mg/dL HDL-C level: Men: <40 mg/dL Women: <50 mg/dL	Plasma triglyceride level >1.7 mmol/L (150 mg/dL) and/or HDL-C level: Men: <0.9 mmol/L (35 mg/dL) Women: <1.0 mmol/L (40 mg/dL)
Obesity	Waist circumference Men: >40 inches Women: >35 inches	BMI >30 kg/m ² and/or waist/hip ratio: Men: >0.90 Women: >0.85
Glucose	Fasting blood glucose level >110 mg/dL	Type 2 diabetes or impaired glucose tolerance (IGT)
Other		Microalbuminuria (overnight urinary albumin excretion rate >20 µg/min [30 mg/g Cr])
Requirements for diagnosis	Any three of the above disorders	Confirmed type 2 diabetes or IGT and any two of the above criteria. If normal glucose tolerance, must demonstrate three of the above criteria.

Section VII

Putting It All Together

Table 37.5 Expanded Definition and Criteria: Metabolic Syndrome

Major Criteria	
Fasting glucose	>110 mg% or hemoglobin A1C over 6.5, 2 hour PPG >140 mg%, fasting C-peptide elevated
Abdominal obesity (visceral)	Waist circumference: Men: >40 in (102 cm); Women: >35 inches (88 cm) Waist-Hip ratio: Men: >0.90; Women: >0.85 Body Fat: Men: >29% (normal is <16%); Women: >37% (normal is <22%) BMI over 30 kg/m ²
Dyslipidemia (atherogenic)	TG >130 mg% (large VLDL) (optimal is <75 mg%) HDL: Men: <40 mg%; Women: <50 mg% (small HDL) TG/HDL ratio >3.0 Small dense type B LDL with increased LDL particle number exceeding 900 (NMR) Elevated Lp(a)
Hypertension	BP >135/85 mm Hg (24 hour ABP monitoring with BP load, mean, circadian cycle and nocturnal dipping) (optimal BP 110/70 mm Hg)
Microalbuminuria	>30 mg in 24 hours or >20 ug/minute or albumin creatinine ratio >30 mg/g
Prothrombotic state	PAI-1, increased platelet activation and aggregation, fibrinogen, von Willebrand factor, Factor VII, thrombin
Insulin resistance and hyperinsulinemia	Fasting insulin, proinsulin, C-peptide
Proinflammatory state	HS-CRP, fibrinogen, IL-6, IL-1B, TNF- α , leukocytosis
Minor Criteria	
Endothelial dysfunction	
Abnormal arterial compliance	Especially small resistance arteries, low C2 compliance and increased pulse wave velocity
Left ventricular hypertrophy and diastolic dysfunction	
Hyperuricemia	
Increased vascular oxidative stress	>9 ug/L
Homocysteine	
Objective evidence of accelerated atherogenesis for age-matched gender, ethnicity and age	
Abnormalities in autonomic nervous system regulation and activation of the cardiovascular system	
Important Points	
1. This is a continuum of risk starting at BP of 110/75 mm Hg, FBS of 75 mg%, LDL of 60 mg%, TG of 75 mg%, declining HDL from 85 mg% and homocysteine of 5 μ g/L. Insulin resistance and the metabolic syndrome do not start at an arbitrary cutoff level.	
2. 25–30% U.S. population have metabolic syndrome.	
3. Common pathogenetic factors to type 2 diabetes mellitus exist in the metabolic syndrome.	
Definition for Confirmed Diagnosis	
1. Three major criteria	
2. Two major criteria plus two minor criteria	

Insulin mediates metabolic, mitogenic and vasodilatory-vascular functions in skeletal muscle and adipose tissue, but also in the liver, brain, heart, blood vessels, pancreas, and other tissues.^{142,143,144,145} Insulin resistance results in an imbalance of the mitogen-activated protein kinase (MAPK) and phosphatidylinositol 3-kinase (PI3-K) pathways (Figure 37.4), which promotes cell proliferation and migration, thrombosis, and inflammation with increased cytokines and cell adhesion molecules. An imbalance in these pathways also reduces glucose transport in insulin-dependent tissues and decreases endothelial nitric oxide synthase/nitric oxide bioactivity.^{146,147,148,149} The enhanced MAPK pathway is proatherogenic, which overrides the antiatherogenic PI3-K pathway. The roles of the insulin receptors, the mitochondria, the pancreatic beta cells, inflammatory cytokines, radical oxygen species (ROS), and free fatty acids are important in the clinical expression of insulin resistance and type 2 diabetes. Chronic insulin resistance, when followed by beta cell dysfunction and failure, eventually produces type 2 diabetes.^{150,151,152,153}

Figure 37.4 Stimulation of the MAPK pathway in endothelial and VSM cells

Adipose tissue is an endocrine organ that produces a variety of “adipokines,” including inflammatory mediators and hormones that result in chronic inflammation, endocrine and metabolic dysfunction that manifests as insulin resistance, and the clinical diseases of hypertension, dyslipidemia, hyperglycemia, diabetes, and CVD.^{154,155}

The adipocytes are both the source and the target of proinflammatory signals from various mediators such as angiotensinogen, A-II, intracellular cell adhesion molecules (ICAM), interleukin-6 (IL-6), interleukin 1B (IL-1B), prostaglandin E-2 (PGE-2), monocyte chemoattractant protein-1 (MCP-1), colony stimulating factor-1 (CSF-1), macrophage inflammatory protein-1 alpha (MIP-1 α), tumor necrosis factor-alpha (TNF- α), complement 3 (C₃), resistin, ASP (acetylation stimulating protein), leptin, FFA, lipoprotein lipase, adiponectin, chemotaxin, plasminogen activator inhibitor-1 (PAI-1) tissue factor, and other mediators.^{156,157,158} The subsequent increase in high sensitivity C-reactive protein (hs-CRP is both a risk factor marker and a mediator) is highly correlated with future cardiovascular events.¹⁵⁹ The role of peroxisome proliferator activated receptors (PPAR) alpha and gamma are important in insulin resistance, glucose and lipid metabolism, and overall vascular function, inflammation, atherosclerosis, and hypertension.¹⁶⁰

Prevention and Treatment

Prevention and treatment approaches for the metabolic syndrome and its components include early detection, aggressive nutritional intervention, nutraceuticals, supplements, vitamins, antioxidants, minerals, functional foods, weight management, aerobic and resistance exercise, moderation of alcohol ingestion, discontinuation of all tobacco products, and limited caffeine.^{161,162,163}

A 6.5% weight loss reduces BP 11/6 mm Hg, glucose 17 mg/dL, triglycerides 94 mg/dL, total cholesterol 37 mg/dL at one month.¹⁶⁴ These changes are sustained with further decreases in BP and triglycerides at four months.¹⁶⁵ Exercise improves all components of the metabolic syndrome.^{166,167,168,169,170,171,172,173,174,175,176,177,178}

Nutritional supplement recommendations are outlined in Table 37.6.¹⁷⁹ Pharmacologic therapy with antihypertensive, antidiabetic, antilipid, and anti-inflammatory medications may be required to achieve new target goals in all of the various risk factors. Although the treatment goals for risk factors continue to change, optimal goals are yet to be established. In the author's opinion, new aggressive optimal goals to achieve the best reduction in cardiovascular events are: BP <110/75 mm Hg, fasting blood glucose (FBG) ~75 mg%, LDL-C $\leq$ 60 mg%, triglyceride (TG) $\leq$ 75 mg%,

Section VII

Putting It All Together

HDL >85 mg%, homocysteine <5 micromoles/L, and hs-CRP <1.0.

Table 37.6 Nutritional Supplements and Lifestyle Recommendations for Treatment of the Components of Metabolic Syndrome

1. Nutrition—establish target goals for:
Protein, fat, carbohydrates: type, composition, percentage of calories from each source
Glycemic index and glycemic load
Fiber
Calories
2. Weight loss and visceral abdominal fat reduction
3. Exercise: aerobic and resistance
4. Nutritional supplements
Alpha-lipoic acid
Biotin
Carnitine
Chromium and glucose tolerance factor (GTF)
CoQ10
Flavonoids
Folate
GLA
Glutathione
Green tea (contains epigallocatechin gallate, or EGCG)
Inositol
Magnesium
Manganese
MUFA (oleic acid)
N-acetyl cysteine (NAC)
Niacin and niacinamide
Omega-3 FA
Potassium
Pycnogenol
Selenium
Taurine
Vanadate
Vitamin B12
Vitamin B6
Vitamin C
Vitamin E derivatives
Zinc

Angiotensin-converting enzyme inhibitors (ACEIs), angiotensin-receptor blockers (ARBs), and calcium channel blockers (CCBs) have the best overall profile for the pharmacologic treatment of hypertension.^{180,181} The ACEIs and ARBs are preferred for patients with proteinuria or renal insufficiency. Thiazide, thiazide-like diuretics, and beta blockers may have adverse effects on glucose and lipid metabolism and should be reserved for resistant hypertension or compelling indications.¹⁸²

Indapamide is the preferred diuretic in the metabolic syndrome due to its better antihypertensive effect and minor or no adverse effects on glucose, lipids, potassium, uric acid or renal function.^{183,184,185,186} Alpha blockers and central alpha agonists may be used, but are limited due to clinical side effects.

Statins, fibrates and niacin should be used as pharmacologic monotherapy or in combination for patients with various forms of dyslipidemia.^{187,188,189}

Metformin and thiazolidinediones are the preferred pharmacologic treatment of insulin resistance, glucose intolerance and type 2 diabetes, as they increase insulin sensitivity, reduce insulin levels, and improve glucose.^{190,191,192}

A combination of vitamin B6 25 µg qd, B12 1,000 µg qd, and folate 800 µg qd is usually optimal treatment for elevated levels of homocysteine. Low-dose aspirin (81 mg/day), omega-3 fatty acids, mixed tocopherols, garlic (allicin), statins, ACEIs, ARBs, and possibly CCBs should be used to prevent thromboembolic problems, CVD, cardiovascular atherosclerosis, and reduce inflammation and hs-CRP.

Summary

The metabolic syndrome is an insulin-resistant state associated with lipotoxic visceral obesity, nutritional deficiencies, and unhealthy lifestyles that induce inflammation, oxidative stress, and immunologic abnormalities. It is a common condition, increasing in incidence, and is associated with a high risk of CVD. Effective management requires aggressive recognition, prevention, and treatment of CVD risk factors and identifiable vascular disease. Lifestyle modifications (improved diet and nutrition, weight loss, increased exercise), nutritional supplements, and pharmacologic therapy to achieve new goal levels of BP, lipids, glucose, and homocysteine will reduce cardiovascular complications.

2010 Update Note: The cases you are about to read, on psoriatic arthritis and ADHD, have been structured to exemplify the functional medicine process and architecture from several perspectives. Each has a Full Case narrative, a Functional Medicine Matrix Form, and a one-page Case at a Glance. Both cases have also been published in *Alternative Therapies in Health and Medicine* and *21st Century Medicine: A New Model for Medical Education and Practice*. We hope that by disseminating these cases widely, we can contribute to the broader adoption of functional medicine by many more practitioners of all disciplines. We welcome submission by readers of new cases using this structure; we will give them every consideration for use in future IFM publications.

—The Editors

Full Case: Psoriatic Arthritis*

Kara N. Fitzgerald, ND, and Mark Hyman, MD

*This case was assembled and edited by The Institute for Functional Medicine with the gracious support of Metametrix Clinical Laboratory and The UltraWellness Center.

Functional Medicine and Autoimmune Disease

Autoimmune diseases collectively affect up to 23.5 million Americans.¹ They are heterogeneous in pathology but relatively uniform in etiology. Classifying autoimmune diseases based on symptoms and pathology does not usually improve treatment decisions. Standard treatments include NSAIDs, steroids, anti-neoplastic agents, and tumor necrosis factor-alpha antagonists. These tools have significant risks and are often applied regardless of the diagnosis. Frequently, they are only modestly effective in relieving symptoms and limiting the advancing disease process. Despite the extensive categorization of autoimmune diseases into diagnoses such as lupus, rheumatoid arthritis, psoriatic arthritis, inflammatory bowel disease, multiple sclerosis, nephritis, and scleroderma, the treatments are based on pathology, not etiology. The conventional approach to autoimmune disease seeks to answer the question of WHAT disease the patient has, not WHY the patient has the disease, suggesting only small variations in treatment.

Functional medicine considers the diagnosis, of course, but also seeks to answer the question WHY. The etiology of any disease may be different in people with the same diagnosis or pathology. Conversely, the etiology may be the same in patients with very different pathologies—for example, mercury toxicity is found in both multiple sclerosis and Crohn's disease. Approaches to treatment, therefore, will vary when the upstream causes and downstream effects differ from patient to

patient. Treating only the downstream effects (such as nutrient deficiencies or food sensitivities due to malabsorption and intestinal hyperpermeability) without treating the upstream causes (such as gluten sensitivity, gastrointestinal yeast, or mercury toxicity) will often result in treatment failure.

Focusing on the patient's individual etiology of autoimmune disease provides a personalized framework for diagnosis and treatment. There are 5 primary etiologic factors that affect gene expression and give rise to nearly all disease, including autoimmune disease: toxins, allergens, infections (or microbial imbalances), poor diet, and stress.

Findings and Assessment at Initial Visit

History of Present Illness

At age 56, MP presented with a 4-year diagnosis of psoriatic arthritis that was progressively worsening despite aggressive medication therapy. He experienced severe pain, decreased range of motion, and swelling in his feet, ankles, knees, and hands. He walked with a limp. His left shoulder was also frequently painful. All symptoms were worse in the morning. He had been taking etodolac (Lodine®) and methotrexate for the past 3 years, and adalimumab (Humira®) for the past 6 months. The onset of psoriatic arthritis began with the development of pain and redness in his right great toe, for which he was treated unsuccessfully with antibiotics. Shortly thereafter, he developed psoriasis behind his knees, on his feet, and behind his ears. He had psoriatic nails for most of his life.

Just prior to receiving the diagnosis of psoriatic arthritis, he had a left knee arthroscopy that was negative for degenerative disease but positive for synovitis. He also developed a hemorrhagic Baker's cyst, causing severe swelling and pain in his left foot and knee. MP

also complained of esophageal reflux, a recent 15-pound weight gain, and intermittent depression.

Past Medical History

Migraine headaches

Disc protrusion with sciatica at L5-S1

Family Medical History

- MP's mother is alive at age 82; she has been diagnosed with congestive heart failure, malnutrition, rheumatoid arthritis, depression, and schizophrenia.
- MP's father died at age 62; he had cancer, obesity, and alcoholism.
- MP's brothers have been diagnosed with cancer, inflammatory arthritis, inflammatory bowel disease, alcoholism, and depression.
- His sisters have alcoholism, depression, and bipolar disorder.
- The maternal grandmother died at 80; she had been diagnosed with hypertension, diabetes and depression.
- The paternal grandmother died at 70; she had heart disease, hypertension, obesity, and diabetes.
- The paternal grandfather died at 80; he had heart disease, hypertension, obesity, and diabetes.
- MP's son has schizophrenia and his daughter has ADHD.

Medications and Supplements

Etodolac (Lodine) 500 mg; 1 tab PO QD

Methotrexate 2.5 mg; 6 tablets per week

Adalimumab (Humira) 40 mg/0.8 mL; 1 SQ injection every other week

Aspirin 81 mg; 1 tablet PO QD

Zolpidem (Ambien®) prn

Omega-3 EPA 1000 mg; 1 capsule PO QD

Multivitamin and mineral; 1 tablet PO QD

Past history of multiple courses of antibiotics

Social History

MP leads a stressful life with a highly demanding job as a university professor and researcher. His schedule leaves little time for relaxation, although he does meditate daily. MP is married with 2 children, including one who has been diagnosed with schizophrenia and lives at home.

Nutrition, Exercise, and Environmental Exposures

Usual Dietary Intake

Breakfast: oatmeal with low fat milk, brown sugar

Lunch: tuna wrap or soup with cookies

Dinner: fish or meat, vegetables, potato or pasta, occasional salad with commercial salad dressing

Snacks: cookies or protein bars

MP avoids chocolate and fatty foods. He eats out more than 5 times per week. He craves sweets and caffeine. MP consumes 3–4 cups of coffee and one diet soda per day (357–464 mg caffeine). MP drinks approximately 12 alcoholic beverages per week, including wine and the occasional scotch. MP reported that his liver enzymes have been elevated, and he has some concern about his drinking.

Exercise

MP does not engage in exercise due to his long days, but is motivated to start.

Environmental Exposures

Many mercury amalgams

Mold exposure

Systems Review

General: 15-pound weight gain

HEENT: Sensitive to loud noises; dry eyes with crusty secretions; intolerant of cigarette smoke, perfumes, and auto exhaust; canker sores; esophageal reflux

GI: Chronic constipation

MSK: Tendonitis

M/E: Intermittent depression, difficulty concentrating, irritability

Significant Physical Exam Findings

Blood pressure 138/87 (LAS)

Height 70.5"

Weight 204 pounds

Body mass index 28.85

Waist circumference 40"

Hip circumference 43"

Waist-hip ratio 0.9

Initial Assessment and Laboratory Recommendations

Organized According to the Functional Medicine Matrix

Initial Clinical Assessment	Laboratory Tests Ordered
<i>Immune Surveillance and Inflammatory Process</i>	
Psoriatic arthritis Psoriasis Psoriatic nails Blepharitis Aphthous stomatitis	1. HLA DQ2 and DQ8 genotypes 2. Celiac panel 3. IgG food sensitivities 4. Inflammatory/autoimmune panel with Iron 5. Vitamin D 6. Omega-3 and 6 fatty acids 7. Lipid peroxides (oxidative stress marker) 8. RBC magnesium
<i>Hormone and Neurotransmitter Regulation</i>	
Depression Family history of heart disease, hypertension, psychiatric disorders, diabetes	9. Comprehensive metabolic panel with fasting glucose & insulin, HgbA1C 10. Lipids 11. Saturated and monounsaturated fatty acids 12. Thyroid panel
<i>Digestion and Absorption</i>	
Gastroesophageal reflux disease Chronic constipation Yeast overgrowth Migraines Family history IBD	13. DNA microbial stool analysis with chemistries *HLA DQ, IgG foods, celiac panel
<i>Detoxification and Biotransformation</i>	
Mercury toxicity (multiple amalgams)	14. Whole blood toxic metals 15. Urine toxic metals challenge test (with DMPS chelating agent)
<i>Psychological and Spiritual Equilibrium</i>	
High-stress work life Depression Family history of psychiatric illness	*Vitamin D, omega-3 and -6 fatty acids, thyroid panel
*Laboratory tests frequently pertain to multiple areas of imbalance, and therefore may be listed in more than one Matrix category.	

Significant Laboratory Findings

Organized According to the Functional Medicine Matrix

Immune Surveillance and Inflammatory Process	
Test	Results
1. DQ Genotype	Allele Detected: HLA DQA1*0501

Psoriatic arthritis is associated with celiac disease and subclinical gluten enteropathy.² HLA DQ is a heterodimer cell surface type protein found on antigen-presenting cells. There are 9 serotypes of DQ proteins. Approximately 90% of celiac patients express the DQ2 heterodimer serotype, and approximately 7% of patients express the DQ8. The DQ2 heterodimer is encoded by the DQA1*0501 and the DQB1*0201 alleles; DQ8 is encoded by the DQA1*0301 and the DQB1*0302 alleles. More than 3% of celiac patients present with half the DQ2 heterodimer. In one study looking at 1008

European celiac patients, 61 were identified who carried neither the DQ2 nor DQ8 heterodimers; 57 of these encoded half of the DQ2 heterodimer.³

MP's test results demonstrated the presence of half the DQ2 heterodimer—specifically, the HLA DQA1*05 allele. Thus, celiac disease could not be ruled out based on this finding. HLA DQ susceptibility is carried by about 30-40% of the population, but only 1% manifest with frank celiac disease.

Test	Results	Reference Interval
2. Celiac Disease Panel		
Immunoglobulin A	438	82–453 mg/dl; OR 10 mg/dL
Transglutaminase IgA	<20	<20 Units

IgA tissue transglutaminase antibodies (TTG) were undetectable, reducing the likelihood of celiac disease. However, antigliadin IgA and IgG antibodies may detect

milder gluten intolerance. Unfortunately, though ordered, the laboratory did not perform these tests.

Test			
3. IgG (total) Reactive Foods*			
Almond (+2)	Chili Pepper (+2)	Lobster (+1)	Sesame (+1)
Amaranth (+1)	Clam (+2)	Milk, Cow's (+2)	Shrimp (+1)
Barley (+1)	Corn (+1)	Onion (+1)	Tomato (+1)
Bean, Kidney (+1)	Crab (+1)	Oyster (+2)	Wheat (+2)
Cantaloupe (+1)	Cranberry (+1)	Pineapple (+1)	Yeast, Baker's (+3)
Cashew Nut (+1)	Egg (+3)	Potato, White (+1)	Yeast, Brewer's (+4)
Cheese (+1)	Garlic (+1)	Scallops (+2)	
* Results range from 0 (no reaction) to +5 (severe reaction).			

ELISA testing for total IgG response to 90 different foods demonstrated a strong positive reaction to eggs and yeast, and mild positive reactions (+1 or +2) to 25 other foods, including gluten-containing wheat and barley. Food sensitivities generate significant inflammation, and as such are both a cause and effect of intestinal hyperpermeability.⁴⁻⁶ Other factors contributing to intestinal hyperpermeability included alcohol and NSAID use.^{7,8}

Despite the equivocal celiac panel discussed above, a gluten-free trial was suggested because of the positive IgG reaction to wheat and barley and the presence of the DQ2 allele. It was also recommended that he eliminate dairy and those foods with reactivity of +3 and above, and limit intake of the other +2 foods.

Test	Results	Reference Interval
4. Inflammatory Markers		
Iron	80	50–150 mcg/dL
Transferrin	246	201–336 mg/dL
TIBC	308	255–450 mg/dL
Iron saturation	26	20–50%
Ferritin	322	HN 23–336 ng/mL
ESR Westergren	7	0–20 mm/hr
CRP High Sensitivity	2.9 mg/L	H Relative Cardiovascular Risk: Low <1.0; Average 1.0–3.0; High 3.1–10.0
Rheumatoid Factor	<20	<30 IU/mL
ANA Screen	Negative	Negative

With the exception of a high-normal ferritin and elevated hs-CRP, none of the inflammatory markers were abnormal. Methotrexate and adalimumab

(Humira) attenuate markers of inflammation, and may have been responsible for these negative findings.^{9–11}

Test	Results	Reference Interval
5. Vitamin D 25 OH	21 ng/mL	L < 20 ng/mL: Insufficiency 20–40 ng/mL: Hypovitaminosis D 40–100 ng/mL: Sufficiency > 100 ng/mL: Toxicity

The pathophysiology of psoriatic arthritis includes upregulation of Th1-driven inflammation. Vitamin D specifically regulates T-helper and dendritic cell function while inducing regulatory T-cells, causing a decrease in Th1 activity.^{12, 13} MP's low serum vitamin D level may have contributed to the severity of his

symptoms. The optimal serum vitamin D range is now thought to be 40–70 ng/mL. Individuals with chronic disease should maintain levels between 55 and 70 ng/mL.¹⁴ Hypovitaminosis D may also have played a role in MP's depression.¹⁵

Test	Result uM	80% and 95% Reference Intervals
6. Plasma Omega-3 and -6 Fatty Acids		
Omega-3 fatty acids:		
Alpha linolenic acid (ALA)	60	>37; 22–144
Eicosapentaenoic acid (EPA)	105	>44; 19–362
Docosahexaenoic acid (DHA)	327	>172; 95–333
Omega-6 fatty acids:		
Arachidonic acid (AA)	739	H 330–630; 260–750

Probably because MP was supplementing them, the omega-3 fatty acids (ALA, EPA, and DHA) were all within normal limits. However, the omega-6 fatty acid AA was high normal, supporting the production of pro-inflammatory cytokines. The 2- and 4-series eicosanoids, produced from AA, stimulate the upregulation of TNF-alpha, a Th1 cytokine strongly implicated in psoriatic arthritis pathogenesis.¹⁶ MP was taking the drug adalimumab (Humira), which binds TNF-alpha directly, blocking its ability to bind certain receptors.¹⁷ Reducing AA could assist in modulating the inflammatory effects of psoriatic arthritis by reducing AA-derived eicosanoids.

MP also demonstrated signs of insulin resistance (discussed further below). It has been suggested that insulin stimulates the production of AA,¹⁸ and AA elevation has been associated with insulin resistance.^{19,20} These findings suggest a mechanistic link between psoriatic arthritis and metabolic syndrome. An elevated AA/EPA ratio has been shown to positively correlate with depression.²¹ MP had more than 7 times the amount of AA relative to EPA in his plasma, despite supplementation with omega-3 fatty acids.

Test	Results		Optimal and 95% Reference Intervals
7. Lipid Peroxides (serum)	1.6 nmol/mL	H	<1.5; ≤2.0
8. Magnesium (RBC packed cells)	25 ppm	L	>26; 18–40

Elevated serum lipid peroxides demonstrated oxidative stress. Sub-optimal magnesium is found in a large

percent of the population, and is a common finding in those with chronic disease.²²

Hormonal and Neurotransmitter Regulation

Test	Results		Reference Interval
9. Comprehensive Metabolic Panel:			
Glucose	106	H	70–99 mg/dL
Insulin	21	H	6–27 uIU/mL (ORI: 0.1–5.0) ²³
Glycohemoglobin A1C	5.5		4.4–6.8%
ALT	44	H	0–40 IU/L
10. Lipids:			
Cholesterol, Total	218	H	< 200 mg/dL
Triglycerides	431	H	< 150 mg/dL
Cholesterol, HDL	43	LN	40–59 mg/dL
Cholesterol, LDL	Not done due to interference of elevated triglycerides		< 130 mg/dL

MP's lab findings met the American Heart Association guidelines for the diagnosis of metabolic syndrome: elevated fasting blood glucose, triglycerides, and blood pressure, with low HDL.²³ The elevated ALT suggested early fatty liver disease.²⁴ A triglyceride/high-density lipoprotein ratio greater than or equal to 3.5 was suggestive of insulin resistance, and an increased likelihood of coronary artery disease.^{25, 26} A fasting insulin

between 18.56 and 225 has been associated with a significantly greater risk for cardiovascular disease as compared to a fasting insulin between 0.1–5.0.²³ An association between psoriatic arthritis, dyslipidemia, hypertension, obesity, and insulin resistance has been suggested due to the shared upregulation of inflammatory pathways.²⁷

Test	Result uM		80% and 95% Reference Intervals
11. Saturated and monounsaturated fatty acids			
Plasma saturated fatty acids:			
Palmitic acid	3,408	HN	1,610–2,946; 1,364–3,525
Monounsaturated fatty acids:			
Palmitoleic acid	327	H	< 155; ≤238
Vaccenic acid	208	H	87–175; 74–209
Oleic acid	>2800	H	1,079–2,733; 1,079–2,800

Elevated saturated and monounsaturated fatty acids represent a pattern seen in metabolic syndrome with hypertriglyceridemia, where insulin stimulates the liver enzyme fatty acid synthase to produce saturated fatty

acids. Insulin also stimulates delta-9 desaturase, which converts saturated to monounsaturated fatty acids, primarily palmitoleic, vaccenic, and oleic.²⁸

Test	Result		Reference Interval
12. Thyroid Panel			
TSH	2.39	HN	0.28–3.89 mIU/L
T4, Free	0.58	LN	0.58–1.64 ng/dL
T3, Free	2.9	LN	2.5–3.9 pg/mL
Thyroglobulin Ab	< 20		< 40 IU/mL
Thyroid Peroxidase Ab	< 20		<35 IU/mL

MP’s thyroid panel was within normal limits, including antibodies. Optimal TSH is now considered to be 2.5, but may be as low as 1.18 mIU/L.²⁹ Free T3 and free T4 were low normal. These results suggested that the thyroid should be monitored, particularly given the

association of hypothyroidism with rheumatologic conditions. Nutrients involved with thyroid function, including red blood cell zinc, whole blood selenium, and plasma tyrosine, were within normal limits.

<i>Digestion and Absorption</i>	
Test	Result
13. DNA microbial stool profile	
Candida sp.	+3 ≥10,000 pg DNA/g specimen H

As suspected, DNA stool analysis demonstrated a significant quantity of Candida species in the gastrointestinal tract. Candida species in particular have been

found in significant amounts relative to controls in the saliva, skin, and stool of psoriatic patients.³⁰

<i>Detoxification and Biotransformation</i>
Given MP's high number of amalgams, there was concern about mercury. According to the CDC, up to 75% of an individual's mercury exposure may be released from amalgams. ³¹ Whole blood toxic metals (Test #14) were within normal limits, ruling out significant current release from amalgams. A DMPS-challenged urine toxic element test (Test #15) was also ordered to assess body burden, but MP had not completed the test at the time of this publication.

Summary of Initial Assessments, Laboratory Findings, Treatments, and Treatment Rationale

Organized According to the Functional Medicine Matrix

Immune Surveillance and Inflammatory Process			
Clinical Assessment and Diagnoses	Laboratory Results	Recommended Treatment	Treatment Rationale
- Gluten sensitivity - Intestinal hyperpermeability - Multiple IgG food sensitivities - Hypovitaminosis D - Psoriatic arthritis - Psoriasis - Psoriatic nails - Blepharitis - Aphthous stomatitis - Family history of autoimmunity	+ celiac gene (HLA DQ2) + IgG to 27 foods - Low serum vitamin D - Elevated plasma arachidonic acid - Elevated serum lipid peroxides - Low RBC magnesium	- Anti-inflammatory medicinal food; 2 scoops QD - EPA/DHA 6:1; 1 cap BID - Vitamin D3 5000IU; 2 caps QD Dietary changes: 100% gluten and dairy free. - Avoid yeast and eggs. - Eat whole, low glycemic index foods, good fats and protein. - Discontinue alcohol, caffeine, sugar.	- Intended to reduce GI inflammation and intestinal permeability - Anti-inflammatory omega-3 fatty acids used to minimize pro-inflammatory events supported by high arachidonic acid - Serum vitamin D goal: 55–70 ng/mL - Dietary changes are based on clinical history, IgG food sensitivities, HLA DQ2 status, elevated metabolic markers, and GI yeast overgrowth *Also supportive: probiotics and multivitamin and mineral

Hormone and Neurotransmitter Regulation

Clinical Assessment and Diagnoses	Laboratory Results	Recommended Treatment	Treatment Rationale
- Metabolic syndrome - Suspected fatty liver - Subclinical hypothyroidism - Migraine headaches - Depression - Family history of heart disease, hypertension, psychiatric disorders, diabetes	- Elevated triglycerides - Elevated blood glucose - High insulin - Elevated total cholesterol - Low-normal HDL - Elevated ALT - High-normal TSH; low-normal free T3 and free T4	- Methyl donors (B12, folic acid, and B6); 1 cap BID - Amino acids (taurine, glycine, N-acetyl-cysteine, methionine); 3 caps BID - High-dose multivitamin and mineral without iron; 4 tabs BID - Dietary changes as noted under <i>Immune Surveillance and Inflammatory Process</i> (above)	- Methyl donors may be effective for both methylation and sulfuration activity. As such, they are beneficial for mood, cardiovascular and hepatic health - These amino acids support hepatic function, are neuroactive, and may be anxiolytic. - High-dose multivitamin/mineral is used for general micronutrient (cofactor/coenzyme) support - A low glycemic index diet with good sources of fatty acids and proteins is imperative for metabolic issues *Also supportive: EPA/DHA; vitamin D

Digestion and Absorption

Clinical Assessment and Diagnoses	Laboratory Result	Recommended Treatment	Treatment Rationale
- Gastroesophageal reflux disease - Chronic constipation - GI yeast overgrowth - Family history IBD	DNA stool analysis: +3 Candida sp.	450 billion CFU probiotic; 1 packet BID - Fluconazole 100 mg; 1 tab QD x 30 days	- High-dose probiotic therapy supports a healthy microbiota and is beneficial for treatment of autoimmunity, intestinal hyperpermeability, food sensitivities, constipation, GI yeast, and parasitic infections - Yeast overgrowth has been associated with psoriatic arthritis and antibiotic use. Clinical experience dictates long-term fluconazole with dietary changes for best outcome

Detoxification and Biotransformation			
Clinical Assessment and Diagnoses	Laboratory Results	Recommended Treatment	Treatment Rationale
Mercury toxicity (multiple amalgams)	- Negative whole blood toxic metals - Urine toxic metals (MP did not complete this test)	- Methyl donors; 1 cap BID - Amino acids (taurine, glycine, N-acetyl-cysteine, and methionine); 3 caps BID - High-dose multivitamin and mineral without iron; 4 tabs BID	- The blood toxic metals assay was negative, ruling out current exposure. However, there was concern about a mercury body burden from past exposure - Methyl donors and amino acids are helpful in supporting hepatic detoxification of toxic metals - The multivitamin and mineral formula supports detoxification/antioxidant enzymes by providing cofactor and coenzyme nutrients

Psychological and Spiritual Equilibrium

Clinical Assessment and Diagnoses	Laboratory Results	Recommended Treatment	Treatment Rationale
- High-stress work life - Depression - Family history of psychiatric illness	- Low serum vitamin D - Elevated plasma arachidonic acid - High-normal TSH - Low-normal free T3 and free T4	- Continue daily meditation practice - Vitamin D3 5000IU; 2 caps QD - EPA/DHA 6:1; 1 cap BID - Dietary changes as noted under <i>Immune Surveillance and Inflammatory Process</i> (above) - Methyl donors (B12, folic acid, and B6); 1 cap BID - Amino acids (taurine, glycine, N-acetyl-cysteine, methionine); 3 caps BID - High-dose multivitamin and mineral without iron; 4 tabs BID	- Meditation improves general well-being and reduces stress, inflammation, and depression - Hypovitaminosis D and an elevated plasma AA/EPA ratio have been associated with depression - Removing antigenic, inflammatory foods (and alcohol, caffeine, and sugar) supports psychological equilibrium - Methyl donors may be effective for both methylation and sulfuration activity; hence, they are beneficial for mood, cardiovascular and hepatic health - These amino acids support hepatic function, are neuroactive, and may be anxiolytic - High-dose multivitamin/mineral is used for general micronutrient (cofactor/coenzyme) support

*Assessments, laboratory tests and treatments frequently pertain to multiple areas of imbalance and may therefore be listed in more than one Matrix category.

Follow-up Visit at Five Months

MP arrived pain-free the day of the 5-month follow-up visit, stating he hadn't felt so good in years. On average, he reported an 80% reduction in pain with improved mobility. He could climb stairs more quickly and was no longer limping. Morning pain and stiffness were gone. Previously, his hands were swollen and difficult to open. Now, the swelling was resolved and movement was normal. MP had not used any nonsteroidal anti-inflammatories or adalimumab for 2 months. He reduced methotrexate from 15 to 5 mg per week.

His reflux and migraines were gone. His mood had improved and he was less irritable. He was no longer constipated. He reported having a single, well-formed bowel movement daily. He was still under a great deal of stress, working 80 hours a week, but meditation continued to be helpful. He reported he was still getting occasional canker sores.

He quit caffeine and reduced alcohol intake considerably. He started on hypoallergenic prepared meals, which were perfect for his busy lifestyle, enabling him to follow the dietary suggestions. He was taking his supplements regularly. He was losing weight, his clothes fit much better, and he was satisfied with his dietary changes. Overall, he was very pleased with his progress.

The RD/Nutritionist's Comments

Because of his busy lifestyle, the prepared, low glycemic index, hypoallergenic (gluten-, dairy-, and yeast-free), whole-foods meals were a nice match for MP. Indeed, he experienced the greatest symptom relief when he began eating these meals as his primary food source. The dietary changes addressed his metabolic syndrome and provided a good balance of macro- and micronutrients, including vitamins, minerals, protein, and unsaturated fatty acids.

When he reintroduced gluten-containing foods some months later, there was a strong recurrence of arthritic pain and fatigue. It appeared to MP that gluten was a major trigger for his arthritis, which is interesting because the laboratory findings showed eggs and yeast to be the most antigenic foods. MP was counseled on dining out gluten-free since he ate out regularly.

MP was encouraged to eat whole foods high in the nutrients that he was deficient in, so as to minimize long-term dependence on multiple supplements. For

example, nuts, legumes, gluten-free whole grains such as buckwheat, and dark leafy greens are high in magnesium; salmon and sardines are good sources of vitamin D (in addition to sunlight). He was given resources to gradually expand his nutritional portfolio with whole-foods recipes and simple-to-prepare menus. MP was also educated to minimize exposure to factors that contribute to intestinal hyperpermeability, including alcohol and NSAIDs.

Significant physical exam findings on follow-up:

Blood pressure 118/73 LAS (5 months ago: 138/87)

Pulse 58 BPM

Weight 200 pounds (5 months ago: 204)

Case Summary

In this particular patient (MP), gluten sensitivity and yeast overgrowth were the proximal etiologies, with multiple downstream effects including increased intestinal permeability, nutrient malabsorption and deficiency, constipation, GERD, canker sores, blepharitis, psoriasis, and metabolic syndrome (triggered by inflammatory factors). Psoriatic arthritis and psoriasis are often caused by gluten and/or other food sensitivities, yeast overgrowth, or mercury toxicity. These may all serve as triggers for a chronic inflammatory disease and they all need to be addressed in the assessment and treatment. Treating upstream causes and addressing downstream effects is necessary for all chronic illness, especially autoimmune diseases.

Removing gluten, other sensitive foods, and harmful microbes, while replacing missing nutrients and providing compounds to facilitate gut healing, were the core components of this patient's therapy. His unique needs were identified and treated in a personalized approach that models the diagnostic and therapeutic framework for treatment of nearly all chronic diseases using the matrix of functional medicine.

Figure 37.5 Completed matrix form for MP

Case at a Glance: Psoriatic Arthritis		
History of Present Illness		
MP was 56 when he presented to the clinic with psoriatic arthritis. Over the previous year, his symptoms had progressively worsened, with increased pain, decreased range of motion, and swelling in his feet, ankles, hands, and knees. He walked with a limp and had difficulty climbing stairs. His left shoulder was also frequently painful. He was taking etodolac (Lodine®), methotrexate, and adalimumab (Humira®), which did not adequately control his symptoms. He maintained a highly demanding career as a university professor and researcher. He drank alcohol and caffeinated beverages regularly. He meditated 15 minutes each morning. He had a positive family history for rheumatoid arthritis, sero-negative inflammatory arthritis, schizophrenia, and inflammatory bowel disease.		
Abbreviated Assessments, Laboratory Findings, and Treatments Organized According to the Functional Medicine Matrix (Refer to full case presentation for details, including treatment rationale.)		
Clinical Assessment	Laboratory Results	Recommended Treatment
Immune Surveillance and Inflammatory Process		
Gluten sensitivity Intestinal hyperpermeability Multiple IgG food sensitivities Hypovitaminosis D Psoriatic arthritis, nails, skin Blepharitis, aphthous stomatitis FMH: autoimmunity	+ celiac gene (HLA DQ2) + IgG to 27 foods Low vitamin D & magnesium Elevated arachidonic acid & lipid peroxides	Anti-inflammatory medicinal food EPA/DHA Vitamin D3 Dietary changes: Gluten and dairy free. Avoid yeast and eggs. Eat whole, low glycemic foods, good fats & protein. D/C alcohol, caffeine, sugar.
Hormone and Neurotransmitter Regulation		
Metabolic syndrome Suspected fatty liver Subclinical hypothyroidism Migraine headaches FMH: HD, DM, HTN, psychiatric disorders	Elevated triglycerides, FBS, insulin, cholesterol Low-normal HDL Elevated ALT High normal TSH	Methyl donors (B12, folic acid, and B6) Amino acids (taurine, glycine, N-acetyl-cysteine, methionine) High-dose multivitamin and mineral without iron Dietary changes as noted above
Digestion and Absorption		
GERD Chronic constipation GI yeast overgrowth Family history IBD	DNA stool analysis: +3 Candida sp.	450 billion CFU probiotic Fluconazole 100 mg; 1 tab QD x 30 days
Detoxification and Biotransformation		
Mercury toxicity (multiple amalgams)	Negative whole blood toxic metals Urine toxic metals challenge test not completed	Methyl donors (B12, folic acid, and B6) Amino acids as noted above High-dose multivitamin and mineral without iron
Psychological and Spiritual Equilibrium		
High-stress work life Depression Family history of psychiatric illness	Low serum vitamin D Elevated arachidonic acid High-normal TSH Low-normal free T3 and free T4	Continue daily meditation practice Vitamin D3 5000IU EPA/DHA Dietary changes as noted above Methyl donors (B12, folic acid, and B6) Amino acids as noted above High-dose multivitamin and mineral without iron
5-Month Follow-up:		
MP was markedly improved, stating that he hadn't felt so good in years. He reported an 80% reduction in overall pain, with improved mobility and decreased swelling. He was able to walk upstairs and his limp was gone. Morning pain and stiffness were gone. He had not used adalimumab (Humira) for two months and reduced methotrexate from 15 to 5 mg per week. He was following the dietary recommendations and taking the supplements. He eliminated caffeine and reduced alcohol intake considerably.		
Reflux and migraines were gone. His mood improved, and he was less irritable. He lost weight. He was no longer constipated. He was still under a great deal of stress, working 80 hours a week, but meditation continued to be helpful.		

Full Case: Attention Deficit Hyperactivity Disorder (ADHD)*

Kara N. Fitzgerald, ND, and Mark Hyman, MD

*This case was assembled and edited by The Institute for Functional Medicine with the gracious support of Metametrix Clinical Laboratory and The UltraWellness Center.

Findings and Assessment at Initial Visit

History of Present Illness

LC, 12 years old, presented with attention deficit hyperactivity disorder (ADHD), dysgraphia, environmental allergies, asthma, insomnia, eczema, canker sores, migraine headaches, muscle cramps, stomach pain, nausea and diarrhea. He was first diagnosed with ADHD at age 5. He repeated kindergarten because of attention and behavioral difficulties. He began methylphenidate (Ritalin®) in first grade and continued to take it through fourth grade, although it did not change his behavior significantly. The drug was discontinued in fourth grade due to growth retardation. Off the medication, he gained weight but also increased his intake of junk food and deli meats.

LC had never received a positive teacher's report. Off the methylphenidate, he continued to be disruptive and unfocused. He excelled in math but had severe dysgraphia (Figure 37.5). (Dysgraphia is defined as illegible handwriting and spelling errors and is associated with ADHD.¹) LC's environmental allergy symptoms were sinus congestion, postnasal drip, sore throats, and hives, for which he took cetirizine (Zyrtec®). His mother had removed his bedroom carpet and installed hardwood floors, but there was minimal improvement in his symptoms after these changes. His mother noted that dairy worsened his sinus congestion and postnasal drip. LC usually developed full-blown sinusitis about twice a year, for which he was prescribed antibiotics.

As a toddler, LC had developed asthma, hyperkeratosis pilaris, and eczema. For the asthma, LC was maintained on albuterol, levalbuterol (Xopenex®) and fluticasone (AeroBid®). The asthma caused difficulty with breathing at night, and therefore he did not sleep well. LC also suffered with cold-induced asthma attacks. His skin and anus were frequently itchy, and he got frequent canker sores in his mouth.

LC suffered from migraine headaches with hypersensitivity to light and sound, and had muscle cramps and spasms. For these complaints, he was given acetaminophen and ibuprofen. His stomach pain was treated with cimetidine. He also complained of nausea and had frequent bouts of diarrhea.

Comment: In most realms of psychiatry all the physical problems covered in LC's HPI are considered irrelevant in guiding diagnosis and therapy of brain disorders or ADHD. In looking at his case from a functional perspective, however, they are the most relevant findings in his history and provide clear treatment direction.

Past Medical History

Birth and Infancy

LC was a healthy seven lb, 10 oz baby, but the vaginal delivery was difficult. He was treated for hyperbilirubinemia. LC was breastfed for 10 months, and then he was given soy formula due to a "sensitive stomach." Gluten-containing grains were introduced before one year of age. He was prone to diaper rash, had sensitive skin, and received frequent antibiotics for otitis media as a toddler.

Comment: When introduced into the diet prior to the age of one, gluten-containing grains are associated with a statistically significant increase in the incidence of celiac disease in susceptible patients.² Further, the use of soy formula in infants with a first degree relative with allergies may be associated with increased incidence of allergies, food intolerances and eczema.³ Early antibiotic use is also associated with increased incidence of atopic conditions, including asthma.⁴⁻⁷

Immunizations

LC received a full vaccine schedule, including annual influenza shots.

Trauma

LC sustained a concussion at 5 years old, but the CAT scan was normal.

Family Medical History

LC's mother had migraine headaches, sinusitis, and food allergies. His sister had environmental allergies. LC's father was in good health.

Medications

Cetirizine (Zyrtec)
Albuterol
Levalbuterol Inhaler (Xopenex)
Flunisolide (Nasarel)
Cimetidine (Tagamet®)
Acetaminophen
Ibuprofen

Comment: This is an overwhelming pharmacopoeia for a 12-year-old boy, and his physical, mental, and behavioral symptoms still were not under control. Even the methylphenidate did not significantly help his school performance or behavior or “cure” his ADHD, although it did cause growth retardation, and was therefore discontinued. Side effects of his other medications may also have been involved in the pathogenesis of his complaints. For example, cimetidine has been associated with nutritional deficiencies and gastrointestinal bacterial overgrowth from gastric acid inhibition.⁸ Glutathione depletion results from acetaminophen use⁹; and intestinal permeability increases with use of

nonsteroidal anti-inflammatory medications such as ibuprofen.¹⁰ Flunisolide has also been shown to inhibit growth in children.¹¹

Nutrition and Environmental Exposures

Usual Dietary Intake

Breakfast: eggs and bacon, cereals with soy milk, occasional fruit

Lunch: deli meat sandwiches, cookies, peanut butter and crackers, carrots, and lemonade

Dinner: pizza, pork or chicken, broccoli, green beans, and rice/pasta/potatoes

LC had strong sugar and pasta cravings. He ate candy, cookies, or ice cream on a daily basis, although he felt better when he avoided dairy.

Environmental Exposures

LC's house had an unaddressed mold infestation. The type of mold was unknown. LC had no known drug allergies, but had numerous environmental allergies, including tree pollen and mold.

Initial Assessment and Laboratory Recommendations

Organized According to the Functional Medicine Matrix

Initial Clinical Assessment	Laboratory Tests Ordered
<i>Lifestyle Factors: Nutrient Imbalances</i>	
Nutrient-poor diet Muscle spasms Audio sensitivity Hyperkeratosis pilaris Anxiety ADHD	1. RBC essential minerals 2. Serum vitamins A, E, & beta carotene 3. Serum fatty acids 4. Organic acid B vitamin markers
<i>Immune Surveillance and Inflammatory Process</i>	
ADHD Asthma Allergies Headaches Hives Sinusitis Atopic dermatitis Aphthous stomatitis PMH: diaper rash, otitis media FMH: food and environmental allergies, migraine headaches, sinusitis	5. Vitamin D 6. IgG food sensitivities 7. Celiac panel
<i>Digestion and Absorption</i>	
GERD IBS Pruritus ani > GI yeast infection Nausea Frequent antibiotic use ADHD	8. Complete blood count and metabolic panel (assesses yeast or parasite infection) 9. Organic acids microbial markers *IgG food sensitivities, celiac panel
<i>Detoxification and Biotransformation</i>	
ADHD Food additives	10. 6-hour urine toxic metal challenge test with 250 mg DMPS (2,3-dimercapto-1-propane-sulphonic acid) provocation
<i>Hormone and Neurotransmitter Regulation</i>	
ADHD Dysgraphia Insomnia Anxiety	11. Plasma amino acids 12. Urine neurotransmitter metabolites
*Laboratory tests frequently pertain to multiple areas of imbalance, and therefore may be listed in more than one Matrix category.	

Significant Laboratory Findings

Organized According to the Functional Medicine Matrix

Lifestyle Factors: Nutritional Imbalances			
Test	Results		95% Reference Interval
1. Red Blood Cell Minerals			
Zinc	2.5	L	3.3–7.7 ppm
Magnesium	15	L	18–40 ppm
Copper	260	LN	257–500 ppb
Manganese	22	LN	19–41 ppb
Chromium	1.7	LN	1.4–7.9 ppb

LC was very low in zinc and magnesium; low-normal levels were reported for the rest of the minerals. These findings were not surprising given LC's poor diet, GI inflammation, and cimetidine use. Zinc deficiency is implicated in asthma, atopic dermatitis, allergies, and ADHD.¹²⁻¹⁴ Magnesium deficiency is also implicated in

headaches, insomnia, muscle cramps, and spasms.¹⁵ Copper and manganese are important cofactors in the antioxidant enzyme superoxide dismutase. Chromium as chromodulin may improve cellular glucose uptake by potentiating insulin receptor activity.¹⁶

Test	Results mg/L		95% Reference Interval
2. Serum Vitamins			
Vitamin E	7.2	LN	7.1–31.0
Vitamin A	0.55	LN	0.41–1.5
Beta-carotene	<0.2	L	0.22–2.7

Fat-soluble vitamins were found to be low (vitamins E and A) or undetectable (beta carotene) in LC's serum, including vitamin D (discussed below). While some-

times such a pattern can indicate fat malabsorption, in LC's case this was most likely due to poor dietary habits.

Test	Results uM		80% and 95% Reference Intervals
3. Serum Fatty Acids			
<i>Plasma saturated fatty acids:</i>			
Palmitic	3,425	HN	1,610–2,946; 1,364–3,525
Stearic	951	HN	546–851; 501–1,007
Arachidic	23.0	H	11.3–19.9; 9.7–22.8
Behenic	84	H	31–57; 27–66
Lignoceric	53	H	24–45; 20–52
<i>Plasma trans fatty acids:</i>			
Palmitelaidic	14.5	HN	≤10.8; ≤18.6
Total C:18 Trans	199	HN	≤107; ≤210
<i>Plasma omega-3 fatty acids:</i>			
Alpha linolenic acid (ALA)	60		>37; 22–144
Eicosapentaenoic acid (EPA)	100		>44; 19–362
Docosahexaenoic acid (DHA)	60		>46; 31–112
<i>Omega-6 fatty acids:</i>			
Arachidonic acid (AA)	785	H	330–630; 260–750

Plasma free fatty acids (primarily palmitic acid) roughly approximate plasma triglyceride levels.¹⁷ The numerous high-normal saturated fatty acids indicated that, at 12 years old, LC probably had higher triglycerides as well, most likely caused by insulin-stimulated upregulation of liver fatty acid synthesis. Given LC's high-sugar diet, early onset dysinsulinemia was not surprising. As discussed above, mild chromium deficiency could be another underlying factor contributing to dysinsulinemia.

The elevated *trans* fatty acids (TFAs) were further evidence of LC's poor food choices. TFAs are strongly implicated in metabolic syndrome and cardiovascular disease.¹⁸

Of the polyunsaturated omega fatty acids, the inflammatory eicosanoid precursor arachidonic acid (AA) was very elevated. It was found in much greater quantity than the anti-inflammatory omega-3 fatty acid eicosapentaenoic acid (EPA), creating a relative deficiency of EPA. AA is implicated in the pathogenesis of allergies and asthma,^{19,20} while EPA insufficiency and a low EPA/AA ratio are implicated in ADHD.^{21,22}

Comment: Had LC continued with his presenting diet and lifestyle, the plasma fatty acid analysis reveals the likelihood for continued inflammatory conditions as an adult, including possibly heart disease, diabetes, and cancer. Addressing these findings early not only treated his initial complaints, but significantly reduced his risk for a future of ill health.

Test	Results ug/mg creatinine	80% and 95% Reference Intervals
4. Urinary Organic Acids		
Kynurenate	3.0	HN ≤2.9; ≤4.7
Xanthurenate	0.9	HN ≤0.90; ≤1.50

When elevated, the organic acids above demonstrate a functional B6 insufficiency.²³ A number of LC's symp-

toms may have been attributable to insufficient B6, including ADHD, mood disturbances, and insomnia.²⁴

<i>Immune Surveillance and Inflammatory Process</i>			
Test	Result		Reference Intervals
5. Serum Vitamin D 25 OH	24 ng/m	L	< 20 ng/mL: Insufficiency 20–40 ng/mL: Hypovitaminosis 40–100 ng/mL: Sufficiency > 100 ng/mL: Toxicity

Hypovitaminosis D likely played a role in LC's imbalanced immune response, contributing to both his chronic infections and hypersensitivities. Low vitamin D has been implicated in asthma, general development problems, and mood disorders.²⁵ Optimal serum vita-

min D is now thought to be between 40-70 ng/mL; individuals with serious diseases should maintain levels between 55–70 ng/mL.²⁶

Test
6. IgG (total) Reactive Foods*
Bean, Kidney (+1)
Cheese (+1)
Milk, Cow's (+4)
Mustard (+1)
Peanut (+4)
R. Seed (Canola) (+1)
Walnut (+1)
Yeast, Brewer's (+2)
* Results range from 0 = no reaction to +5 = severe reaction.

ELISA testing for IgG response to 90 different foods demonstrated a strong positive reaction to dairy and peanuts, and mild positive reactions (+1 or +2) to six other foods, suggesting intestinal hyperpermeability

and GI inflammation.²⁷⁻²⁹ These sensitivities may be associated with the pathogenesis of atopic dermatitis, asthma, and ADHD.³⁰⁻³²

Test	Result	95 % Reference Interval
7. IgG antigliadin	17HN	0–19 units

LC’s IgG antigliadin antibodies were trending high at 17 units. Clinical experience warranted minimizing gluten intake.

Digestion and Absorption	
Test #8: Complete Blood Count and Metabolic Panel	LC’s serum chemistries and complete blood count were within normal limits, although his lymphocyte count was higher than his neutrophil count. Clinical experience suggested that this finding, when combined with his history of antibiotic use and complaint of anal itching, probably indicated a fungal or viral infection.
Test #9: Organic Acid Microbial Markers	Surprisingly, LC’s organic acid microbial markers were within normal limits, ruling against significant GI dysbiosis, although he did demonstrate intestinal hyperpermeability with multiple food sensitivities, as discussed above in “Immune Surveillance and Inflammatory Process.”

Detoxification and Biotransformation			
Test	Result ug/g creatinine	95% Reference Interval	
10. Urine Toxic Metals (6-hour challenge test)			
Lead	17	H	≤5

DMPS (2,3-dimercapto-1-propanesulfonic acid) provocation challenge demonstrated an elevated urine lead level in LC. While whole blood is considered the gold standard for identifying lead toxicity, urinary lead concentration has also been shown to increase with toxicity.³³ Chelating agents have been shown to accelerate the urinary excretion of lead and therefore may be useful for revealing lead exposure. Lead exposure may produce cognitive deficits at levels commonly encountered in blood, and therefore numerous recommenda-

tions have been made to reduce safe threshold levels.³⁴ Lead toxicity and environmental toxins such as household mold have been linked to cognitive and behavioral problems in children, including ADHD.³⁵⁻³⁸ Sources of lead include toys, paint, contaminated soil, lead plumbing, and glazed pottery.³⁴ Since essential mineral deficiencies may allow for increased uptake of toxic metals,³⁹ repletion prior to and during treatment of toxicity is important.

<i>Hormonal and Neurotransmitter Regulation</i>			
Test	Result		80% and 95% Reference Intervals
11. Plasma Amino Acids			
Tryptophan	36	LN	>40; 26–62
12. Urine Neurotransmitter Metabolites			
Test	Result ug/mg creatinine		80% and 95% Reference Intervals
Homovanillate	3.0	LN	3.2–16.7; 1.0–23.0
5-Hydroxyindoleacetate	2.6	LN	2.7–14.0 1.2–39.0

The urinary neurotransmitter metabolites for dopamine and serotonin, homovanillate (HVA) and 5-hydroxyindoleacetate (5-HIAA), were low normal in LC, suggesting lower total body neurotransmitter turnover. Corroborative evidence for the risk of serotonin insufficiency was found with low plasma tryptophan, the amino acid precursor to serotonin. Furthermore, 2 important nutrients involved in dopamine and seroto-

nin synthesis, B6 and magnesium, were both reported insufficient in LC (discussed above in “Lifestyle Factors: Nutritional Imbalances”). Genetic and metabolic research has linked imbalances of CNS dopamine and serotonin to ADHD with regard to uptake, synthesis, and breakdown, although there has not been a consistent pattern noted.⁴⁰ Serotonin imbalance has also been implicated in insomnia⁴¹ and IBS.⁴²

Summary of Initial Assessments, Laboratory Findings, Treatments, and Treatment Rationale

Organized According to the Functional Medicine Matrix

Lifestyle Factors: Nutrient Imbalances			
Clinical Assessment and Diagnoses	Laboratory Results	Recommended Treatment	Treatment Rationale
- Nutrient deficiencies - Fatty acid imbalance - Anxiety - Muscle spasms - Audio sensitivity - Hyperkeratosis pilaris	- Low RBC essential minerals - Low serum vitamins A, E, and beta carotene - Elevated plasma AA:EPA ratio - Low B6 (organic acid functional markers) - Elevated plasma saturated and trans fatty acids	- Zinc citrate 20 mg; 1 tab QD - Magnesium glycinate 120 mg; 2 caps QHS - Multivitamin/mineral (MVM); 2 tabs QD - EPA/DHA 6:1; 1 cap BID - Pyridoxal 5' phosphate (activated B6) 50 mg; 1 cap QD - Dietary changes as noted in "Immune Surveillance and Inflammatory Process" below	- MVM for general nutrient needs with extra zinc for immune dysfunction, diarrhea and allergies, and magnesium for muscle cramps, insomnia, anxiety, and auto sensitivity. - Anti-inflammatory omega-3 fatty acid used to minimize pro-inflammatory arachidonic acid cascade as seen clinically with asthma, allergies, dermatitis hyperkeratosis pilaris - B6: evidence supports its use in ADHD, serotonin metabolism, and methylation/sulfuration

Immune Surveillance and Inflammatory Process

Clinical Assessment and Diagnoses	Laboratory Results	Recommended Treatment	Treatment Rationale
• Hypovitaminosis D • Multiple food sensitivities • Intestinal hyperpermeability • ADHD • Asthma • Allergies • Headache • Hives • Sinusitis • Atopic dermatitis • Aphthous stomatitis • PMH: diaper rash, otitis media • FMH: food and environmental allergies, migraine headaches, sinusitis	• Low serum vitamin D • Multiple + IgG food sensitivities • Elevated IgG antigliadin antibodies	• Vitamin D3 1000 U; 1 cap QD • Diet: Modified elimination diet based on test results. No dairy, peanuts, gluten, sugar, or <i>trans</i> fatty acids. Reduce saturated fat intake. Whole foods, minimally processed; organic diet. Organic dark chocolate is fine. (See also Nutritionist Comments below.)	• Serum vitamin D goal: 40–70 ng/mL • Dietary changes based on clinical history, IgG food sensitivities, antigliadin antibodies, intestinal hyperpermeability, fatty acid deficiency, and suspected fungal overgrowth *Also supportive: zinc, magnesium, probiotics

Digestion and Absorption

Clinical Assessment and Diagnoses	Laboratory Results	Recommended Treatment	Treatment Rationale
• Yeast overgrowth • GERD • IBS • Pruritus ani • Intestinal hyperpermeability • Nausea	• Elevated lymphocyte: neutrophil ratio * +IgG food sensitivities, IgG antigliadin antibodies	• Fluconazole 100 mg; 1 tab QD x 30 days • Broad spectrum probiotics; 2 caps Q AM	• Clinical and laboratory evidence for Candida overgrowth. Clinical experience suggests long-term fluconazole with dietary changes for best outcome • Probiotic therapy to support microbiota. Beneficial for treatment of intestinal hyperpermeability and immune hypersensitivity, food sensitivities, and IBS

Detoxification and Biotransformation

Clinical Assessment and Diagnoses	Laboratory Results	Recommended Treatment	Treatment Rationale
- Mild lead toxicity - ADHD - Food additives	Elevated 6-hour urine lead after 250 mg DMPS (2,3-dimercapto-1-propane-sulphonic acid) provocation	- After 2 months on treatment protocol: Start DMSA (dimercaptosuccinic acid) 100 mg, one twice a day, every other week for 3 days (such as MTW), then 11 days off. Do this for 6 months and then repeat the DMPS challenge test - Dietary changes as noted in “Immune Surveillance and Inflammatory Process” above	Oral chelation with DMSA is one of the main treatments for lead toxicity. Pulse dosing DMSA and concurrent detoxification and essential minerals supplementation will minimize adverse reactions. It is important to ensure normal kidney function and bowel movements and treat nutrient deficiencies first, particularly essential minerals, amino acid deficiencies, and impaired methylation

Hormone and Neurotransmitter Regulation

Clinical Assessment and Diagnoses	Laboratory Results	Recommended Treatment	Treatment Rationale
- ADHD - Dysgraphia - Insomnia	- Low-normal plasma tryptophan - Low-normal urine HVA, SHIAA	5HTP 50–100 mg QHS as needed for sleep	5HTP is a serotonin precursor. It will provide substrate for serotonin production while preserving tryptophan. CNS serotonin is methylated to produce melatonin. Increased serotonin may therefore help with insomnia

*Assessments, laboratory tests, and treatments frequently pertain to multiple areas of imbalance and may therefore be listed in more than one Matrix category.

Follow-up Visit at Two Months

After starting his treatment, which included removing yeast and antigenic foods and adding the needed micronutrients and probiotics, LC's mother stated that he was much less disruptive in the classroom. He was sleeping through the night. His headaches and runny nose improved. He hadn't required cetirizine or flunisolide for some time. His asthma symptoms improved and were no longer triggered by cold. Light, sound, and smell sensitivities were reduced considerably. LC tolerated supplements and diet changes well, because he felt so much better when he followed the plan. No changes were made to LC's treatment plan at his 2-month visit.

Follow-up Visit at Six Months

LC's mother reported that he was free from his chronic symptoms for the first time in his life. His dysgraphia improved considerably (see Figures 37.6 and 37.7 for the pre- and post-treatment writing samples). He no longer required his medications, including antihistamines (cetirizine and cimetidine), bronchodilators, steroid inhaler, acetaminophen, and ibuprofen. His mood and behavior had stabilized, and his ability to focus improved greatly. His hyperactivity symptoms, including disruptiveness, irritability, and anxiety, were gone. His hives, asthma, runny nose and postnasal drip, anal itching, stomach aches, nausea, diarrhea, headaches, muscle cramps, and sensitivity to loud noises were all completely resolved. He slept soundly at night. He was doing well in school, academically and socially.

Just after his 6-month follow-up, LC's mother wrote the following:

We had a meeting at LC's school this morning, where the teachers, school counselor, parents, and principal all get together to review "the plan" for kids with special educational needs (in LC's case prompted by the ADHD diagnosis). This was the first time in his entire schooling history that everything seems to be going well. The input from his teachers was that he is "a different kid" than they saw in the first half of the year and that they're amazed by the difference. The school nurse hasn't seen him [in months] (and he used to be in her office several times a week). The school psy-

chologist said his social skills are very good, age appropriate, and that she sees no problems at all. She also noted that LC seems very proud of himself and his new health and that he's taking good ownership of all the changes in his diet. He even seems to be shrugging it off when the other kids at school tell him he's an "alien" because he doesn't drink soda.

This was just such a fantastic meeting and I wanted to pass along the good news and say Thank You!

Laboratory Tests

Follow-up testing revealed normalization of the lymphocyte:neutrophil ratio and improvement in his nutritional status, including normalized levels of vitamin E and beta carotene, RBC minerals, and tryptophan. His saturated fatty acids and *trans* fatty acids were all within their normal ranges, reducing the concern for dysinsulinemia and confirming LC's commitment to following dietary changes. He still required vitamins D and A. The dietary changes and supplement interventions reversed not only his presenting complaints, but radically improved the prognosis for his future health.

The RD/Nutritionist's Comments

LC made remarkable changes, and he was very motivated to do so because he received the immediate feedback of improved health. Most notable, of course, was the resolution of the ADHD symptoms. LC's changes did not come overnight. Indeed, his was a "top-down" change, with his mother making the first moves toward wellness in her life, and experiencing the fruits of good health herself, and then bringing along her family. Wellness of this nature is an ecological shift, like a pebble tossed in a pond that ripples slowly to those around us.

I had been working with LC's mom for a long time before we saw LC. With his mom (as with most people) we started slowly. We did an initial clean-up of the worst (most problematic/toxic) foods in the house, and then removed one problem food per week from her diet. (Sometimes we would negotiate one food change a month. It's important to move at the patient's pace and ability to integrate change.)

Generally, when a child needs to make major dietary changes, it does require the family's buy-in. A significant move away from being unconscious about what we eat toward paying very close attention to where food comes from, what it's made of, the toxin and nutrient content, and the macronutrient composition requires a powerful and intentional return to our roots, how we evolved to eat. We must also pay attention to how we feel after we eat, and notice the impact of food on our health and well-being. We need to have everyone on board in the family, even if only a little, when thinking about food from this perspective. The home front is the nutritional frontier!

To succeed with such changes, the basics need to be addressed:

- Where to shop/what to buy
- How to avoid antigenic foods
- How to replace the foods being eliminated from the diet with healthy alternatives
- How to read and understand food labels
- Identifying hidden food additives and antigens

- "Natural" versus "organic"
- Healthful, affordable foods
- Easy, quick recipe ideas
- Eating healthy on the go
- Eating well at restaurants
- Knowing the nutrient content of foods
- Relying on foods, rather than supplements, for long-term nutrient needs
- Understanding the appropriate balance and quantity of food
- Stress-free eating: rest and digest
- Resources for healthy eating: cookbooks, internet sites

The team approach to treatment in the case of LC was vital to his success. In addition to his medical doctor, he worked with me, a support RN, and of course his mother, father, and siblings. I am not sure we would have seen such a significant turnaround, as demonstrated by his writing specimens, without this approach to care.

Figure 37.6 LC's Pre-treatment writing sample

Figure 37.7 LC's Post-treatment writing sample

Figure 37.8 Completed matrix form for LC

Case at a Glance: ADHD**History of Present Illness**

LC presented at age 12 with attention deficit hyperactivity disorder (ADHD), dysgraphia, environmental allergies, asthma, insomnia, eczema, canker sores, migraine headaches, muscle cramps, stomach pain, nausea, and diarrhea. LC was first diagnosed with ADHD at age 5. He repeated kindergarten because of attention and behavioral difficulties. He began methylphenidate (Ritalin®) in 1st grade and continued to take it through 4th grade, although his behavior did not change significantly. The drug was discontinued in 4th grade due to growth retardation. Off the medication, he gained weight and increased his intake of junk food and deli meats. He continued to have trouble focusing in school and was still disruptive. He had never received a positive teacher report. He had severe dysgraphia, but excelled in math. His medications included: cetirizine (Zyrtec®), albuterol, levalbuterol inhaler (Xopenex®), flunisolide (Nasarel or AeroBid®), cimetidine (Tagamet®), acetaminophen, and ibuprofen. He liked pasta, sweets, and ice cream despite the fact that he felt better avoiding dairy.

Abbreviated Assessments, Laboratory Findings and Treatments
Organized According to the Functional Medicine Matrix
 (Refer to full case presentation for details, including treatment rationale.)

Clinical Assessment	Laboratory Results	Recommended Treatment
Lifestyle Factors: Nutrient Imbalances		
Nutrient deficiencies Fatty acid imbalance Anxiety Muscle spasms Audio sensitivity Hyperkeratosis pilaris	Low essential minerals Low vitamins A, E, beta carotene Elevated AA:EPA ratio Low B6 (organic acid markers) Elevated saturated and <i>trans</i> fatty acids	Zinc citrate Magnesium glycinate Multivitamin/mineral EPA/DHA Pyridoxal 5' phosphate Dietary changes as noted below
Immune Surveillance and Inflammatory Process		
Hypovitaminosis D Food sensitivities Intestinal hyperpermeability ADHD Asthma, allergies, headache, hives, sinusitis Atopic dermatitis Aphthous stomatitis	Low serum vitamin D Multiple + IgG food sensitivities Elevated IgG antigliadin antibodies	Vitamin D3 Dietary changes: Modified elimination diet based on test results. No dairy, peanuts, gluten, sugar, or <i>trans</i> fatty acids. Reduce saturated fat intake. Whole foods, minimally processed, organic diet. (Nutritionist comments available in full case presentation.)
Digestion and Absorption		
Yeast overgrowth GERD, IBS, pruritus ani Nausea	Elevated lymphocyte:neutrophil ratio +IgG food sensitivities, IgG antigliadin antibodies	Fluconazole Broad spectrum probiotics
Detoxification and Biotransformation		
Mild lead toxicity ADHD Food additives	Elevated 6- hour urine lead after 250 mg DMPS (2,3-dimercapto-1-propane-sulphonic acid) provocation	After 2 months on treatment protocol: Start DMSA (refer to full case presentation for details) Dietary changes as noted above
Hormone and Neurotransmitter Regulation		
ADHD, dysgraphia Insomnia	Low-normal plasma tryptophan Low-normal urine HVA, 5HIAA	5HTP 50–100 mg QHS as needed for sleep
6-Month Follow-up: LC's mother reported that he was free from his chronic symptoms for the first time in his life. His dysgraphia improved dramatically (compare Figures 37.6 and 37.7 in full case presentation). He no longer required his medications, including antihistamines (cetirizine and cimetidine), bronchodilators, steroid inhaler, acetaminophen, and ibuprofen. His mood and behavior stabilized, and his ability to focus improved greatly. His hyperactivity symptoms, including disruptiveness, irritability, and anxiety, were gone. His hives, asthma, runny nose and postnasal drip, anal itching, stomachaches, nausea, diarrhea, headaches, muscle cramps, and sensitivity to loud noises were all completely resolved. He slept soundly at night. He was doing well in school, academically and socially (see mother's comments in full case presentation). LC tolerated supplements and dietary changes well, because he felt so much better when he followed the plan.

Biographical Sketches for Contributing Authors

B. Jayne Alexander, DO, is a graduate of the Kirksville College of Osteopathic Medicine located in Kirksville, Missouri. As a student she was awarded an Undergraduate Fellowship in the Department of Osteopathic Theory and Methods and following graduation served a rotating internship at the Kirksville Osteopathic Health Center. Dr. Alexander is Board Certified with Special Proficiency in Osteopathic Manipulative Medicine by the American Osteopathic Association, and is trained in traditional and biodynamic osteopathic approaches. She serves on the faculty of the Sutherland Cranial Teaching Foundation, teaches with the New England-based A. Still Sutherland Study Group, and is a clinical preceptor for osteopathic students, interns and residents. Dr. Alexander has studied functional medicine since 1983, and completed the Institute for Functional Medicine's AFMCP training in 1998 and 2001. She is currently engaged in private practice specializing in osteopathic manual medicine.

Bruce N. Ames, PhD, is a professor of the Graduate School in Biochemistry and Molecular Biology, University of California, Berkeley, and a Senior Scientist at Children's Hospital Oakland Research Institute. A member of the National Academy of Sciences, Dr. Ames served on their Commission on Life Sciences. He was a member of the board of directors of the National Cancer Institute—the National Cancer Advisory Board—from 1976 to 1982. He has received the General Motors Cancer Research Foundation Prize (1983); the Tyler Environmental Prize (1985); the Gold Medal Award, American Institute of Chemists (1991); Award for Excellence in Environmental Health Research (1995); the Honda Prize, Honda Foundation, Japan (1996); the Japan Prize (1997); the Robert A. Kehoe Award, American College of Occupational and Environmental Medicine (1997); the Medal of the City of Paris (1998); the U.S. National Medal of Science (1998); the Linus Pauling Award (2001); and the Thomas Hunt Morgan Medal from the Genetics Society of America (2004). Dr. Ames is among the few hundred most-cited scientists (in all fields), as a result of his 500+ publications.

Sidney MacDonald Baker, MD, is a 1964 graduate of Yale Medical School where he completed his specialty training in pediatrics. He is board certified in pediatrics. He has been a Peace Corps volunteer in Chad, Africa

(1966-1968), an Assistant Professor of Medical Computer Science at Yale (1969-1971), a family physician in the Community Health Care Center (1971-1978) in New Haven, Conn., Director of the Gesell Institute of Human Development (1978-1985), and in private practice in Connecticut and New York. He is co-author of *Child Development* (1982), *The Years from 10 to 14* (1984), and the author of *The Circadian Prescription* (G.P. Putnam Sons, 2000) and *Detoxification and Healing* (Contemporary Books, 2003). He was co-founder in 1995 of the Defeat Autism Now! organization, with Bernard Rimland, PhD and Jon Pangborn, PhD, with whom he is co-author of *Autism: Effective Biomedical Treatments* (2005). Dr. Baker was the 1999 recipient of the Linus Pauling Award from the Institute of Functional Medicine. He is an Associate Editor of *Integrative Medicine: A Clinician's Journal*, and currently practices integrative medicine in Sag Harbor, New York.

Peter Bennett, ND, is a naturopathic physician, best-selling author, and educator. He received his doctorate in naturopathic medicine in 1987 from Bastyr University. In addition to his training as a naturopathic doctor, Dr. Bennett completed a three-year degree program in Traditional Chinese Medicine (TCM) at the Northwest Institute of Acupuncture and Oriental Medicine (NIAOM) in Seattle, WA. He is also a board certified homeopathic physician (DHANP). In 1999, Dr. Bennett co-authored the *7-Day Detox Miracle* (Prima Publishing, 2001), a safe, effective way to help people promote healing, lose weight, and increase energy. Dr. Bennett currently sees patients in Langley, BC where he focuses on providing individual biochemical assessment, and developing programs for optimum performance and recovery.

Jeffrey S. Bland, PhD, FACN, CNS. Dr. Bland's distinguished career in nutritional biochemistry has earned him international acclaim as educator, research professor, leader in the natural products industry, recognized expert in human nutrition and functional medicine, and visionary for the future of health care. Dr. Bland now serves as President and Chief Science Officer of Metagenics, Inc, and Chairman of the Board of Directors for The Institute for Functional Medicine, which he co-founded with his wife, Susan Bland, MA.

John Cline, BSc, MD, utilizes an integrative approach in his medical practice. He is medical director

of the Cline Medical Centre in Nanaimo, British Columbia, Canada. He is also medical director for the Oceanside Functional Medicine Research Institute and has collaborated with Michael Lyon, MD on several research projects related to ADHD. Dr. Cline obtained a BSc in Biochemistry, followed by his MD and residency training in family medicine at the University of Calgary, Alberta, Canada. He has a particular interest in using various detoxification strategies and has taken further training through the American Board of Chelation Therapy, the American Academy of Neural Therapy, and is certified by the International Board of Clinical Metal Toxicology. In April 2005, he completed the physicians training course with the Centers for Advanced Medicine. He is writing a book for the general public about toxicity and detoxification. He has lectured extensively in the community, at medical conferences, and for The Institute for Functional Medicine.

Daniel Cosgrove, MD, earned a psychobiology degree from UCLA and received an MD degree from Washington University in St. Louis. He completed internal medicine training at the University of Utah, and became board certified in both internal medicine and emergency medicine. He holds a clinical faculty appointment at Loma Linda University School of Medicine. Dr. Cosgrove is certified by the Federal Aviation Administration as a Senior Aviation Medical Examiner. He was the Medical Director of Airstar International Air Ambulance for many years. He has published several scientific articles. He is a principal investigator in the KIMS Human Growth Hormone Study. In 1997 Dr. Cosgrove founded the WellMax Center for Preventive Medicine, which is now located at the La Quinta Resort and Club™. WellMax provides executive physicals but is best known for ongoing individualized healthcare, specializing in the early detection of disease through the creation and maintenance of a Personal Health Portfolio.

Walter J. Crinnion, ND, received his degree in naturopathic medicine from Bastyr University (Seattle, Washington) in 1982 with the first graduating class. He opened a family practice and began to specialize in allergies and in treating chronic health problems caused by environmental chemical overload. In 1985 he opened the most comprehensive cleansing facility in North America for the treatment of chemically poisoned individuals. He has published several articles in peer-reviewed journals on the topic of environmental overload. He has served on the board of directors of

the American Association of Naturopathic Physicians and received their first award for in-office research in 1999, and was awarded it a second time in 2002. He is an associate professor at Bastyr University, the National College of Naturopathic Medicine in Portland, OR, and the University of Bridgeport School of Naturopathic Medicine. He is professor and director of the Environmental Medicine Center of Excellence at Southwest College of Naturopathic Medicine. In 2001, he appeared three times with Barbara Walters on ABC's "The View" and had a weekly Health Spot on Northwest Cable News from 1999 until 2003, giving viewers in Oregon, Washington, and Idaho up-to-date information on nutrition and health.

Gary Darland, PhD, received his doctorate in microbiology from the University of Washington. He is Senior Director of Clinical Biology at Metaproteomics, LLC, a division of Metagenics, Inc. Dr. Darland joined HealthComm/Metagenics after 23 years of research experience in natural products, and biochemistry and microbial genetics at Merck Research Laboratories. Research activities at Merck revolved around microbial genetics and physiology and also included work in the area of human and animal drug metabolism. Prior to joining Merck, he was a visiting Fellow at the Centers for Disease Control in the Enteric Disease Section and an assistant professor at California Polytechnic University, San Luis Obispo. These activities have led to the publication of several papers dealing with drug metabolism and the biosynthesis of natural products.

Joel M. Evans, MD, a board certified OB/GYN, is Founder and Director of The Center for Women's Health in Darien, CT, where he practices integrative obstetrics and gynecology. A frequent lecturer on complementary and alternative medicine (CAM), Dr. Evans is an Assistant Clinical Professor of Obstetrics, Gynecology and Women's Health at the Albert Einstein College of Medicine. In January 2001, he was honored as a Founding Diplomate of the American Board of Holistic Medicine. Dr. Evans' book, *The Whole Pregnancy Handbook* (Gotham Books, 2005), details his unique approach to holistic pregnancy care. Dr. Evans is on the senior faculty of The Center for Mind/Body Medicine in Washington D.C. He teaches health professionals about the medical benefits of relaxation therapies at The Center's basic and advanced training programs. He also lectures about nutrition and supplements at the Center's Cancer Guides™ and Food as Medicine conferences. Dr. Evans

has a special interest in helping those affected by the tragedies of war, and participated in the Center's Mind/Body Mission to Macedonia in 1999, where he traveled to U.N. refugee camps to help Kosovar refugees. Dr. Evans also worked with the FDNY firefighters to help them handle the many stresses caused by 9/11.

William J. Evans, PhD, is director of the Nutrition, Metabolism, and Exercise Laboratory in the Donald Reynolds Department of Geriatrics at the University of Arkansas for Medical Sciences and a research scientist in the Geriatric Research, Education and Clinical Center (GRECC) at the Central Arkansas Veterans Healthcare System. He is a Professor of Geriatrics, Physiology, and Nutrition. From 1993 to 1997, he was director of the Noll Physiological Research Center at the Pennsylvania State University and, from 1982 to 1993, he served as Chief of the Human Physiology Laboratory at the USDA Human Nutrition Research Center on Aging at Tufts University. He is a Fellow of the American College of Sports Medicine, The American College of Nutrition, and an honorary member of the American Dietetic Association. Dr. Evans is the author or co-author of more than 190 publications in scientific journals. His research has examined the powerful interaction between diet and exercise in elderly people. He is the co-author of *Biomarkers: The Ten Determinants of Aging You Can Control* (Simon & Schuster, 1991) and authored *AstroFit* (Simon & Schuster, 2002). His work has been featured in numerous newspapers, including *The New York Times*, *The Boston Globe*, and *The Chicago Tribune*.

William B. Ferril, MD, received a Bachelor of Science degree in Biochemistry and his Doctorate in Medicine from The University of California at Davis. He completed his post graduate education at Sacred Heart Medical Center in Spokane, Washington. For over 19 years, Dr. Ferril has practiced medicine on the Flathead Indian Reservation and adjacent areas of Montana. It was during this posting that Dr. Ferril compiled his data for a series of books on the biochemistry of the human body. He is the author of *The Body Heals, Glandular Failure-Caused Obesity*, and *Why is My Doctor So Dumb? Healing 101*. Dr. Ferril resides with his wife and children in Whitefish, MT where he continues research and private practice.

Leo Galland, MD, is the recipient of the 2000 Linus Pauling Award from The Institute for Functional Medicine, for formulating key concepts underlying the discipline of functional medicine. He received his education

at Harvard University and the New York University School of Medicine and trained in internal medicine at the NYU-Bellevue Medical Center. He has held faculty positions at New York University, Rockefeller University, the Albert Einstein College of Medicine, the State University of New York at Stony Brook, and the University of Connecticut. He has written over 30 scientific articles and textbook chapters and has lectured extensively on topics related to nutritional medicine, intestinal health and patient assessment. A board-certified internist, Dr. Galland is a Fellow of the American College of Physicians and the American College of Nutrition, an Honorary Professor of the International College of Nutrition, and has authored three books, *Superimmunity for Kids* (Dell, 1989), *Power Healing* (Random House, 1997), and *The Fat Resistance Diet* (Doubleday, 2006). In addition to a full-time private practice in New York City, Dr. Galland directs the Foundation for Integrated Medicine (www.mdheal.org), and Applied Nutrition, Inc., a medical software company (www.nutritionworkshop.com).

Michael D. Gershon, MD, has published over 300 scientific papers, books, and chapters. His study of the cellular basis of the neuronal control of behavior brought the enteric nervous system (ENS)—discussed in his book, *The Second Brain*—to the attention of the general public and enhanced the esteem in which neurogastroenterologists are held. He was the first to propose, and ultimately to establish, that serotonin is an enteric neurotransmitter, and he has also studied the mechanisms by which the varicella zoster virus infects cells and then is assembled into infectious particles. Dr. Gershon received his BA degree in 1958, with distinction, from Cornell University. Upon graduating from Cornell Medical School in 1963, he was awarded the Polk Prize for the best academic record and the Borden Prize for undergraduate research. He then completed postdoctoral training in pharmacology with Edith Bülbirg at Oxford University (England), before returning to Cornell as Assistant Professor of Anatomy in 1967. He was promoted to Professor before leaving Cornell to accept his current position as Chair of the Department of Anatomy and Cell Biology at Columbia University's College of Physicians and Surgeons.

Patrick Hanaway, MD, is a board-certified family physician with a medical degree from Washington University (St. Louis) and residency training at the University of New Mexico. Dr. Hanaway is also a board-certified holistic physician and currently sits on the American

Board of Holistic Medicine. He received his bachelors degree from the University of Wisconsin in molecular biology and has done research and published papers in muscle biology, neurochemistry, lipid research, digestive disease, public health and prevention. Dr. Hanaway holds dual appointments as Medical Director for Family to Family: Your Home for Whole Family Health (Asheville, NC) and Medical Director for Great Smokies Diagnostic Laboratory. His current interests are in the research and clinical implementation of applied nutritional biochemistry, with an emphasis on digestion, immunology, prevention and wellness.

Bethany Hays, MD, FACOG, is an obstetrician gynecologist with a career-long passion to find the best possible forms of healing and to incorporate them into her practice. That dream has come to a new level of realization with the opening of True North, A Center for Health and Healing, in Falmouth, Maine. This unique integrative practice was created by a group of practitioners of conventional and complementary modalities after nearly four years of dreaming and planning. The addition of functional medicine to her practice has added a new dimension and new excitement for Dr. Hays as well as a passion for the biochemistry she tried so hard to forget after the first year of medical school. She is an adjunct faculty member of The Institute for Functional Medicine, where she also serves on the board of directors.

Robert J. Hedaya, MD, is a Fellow of the American Psychiatric Association and Clinical Professor of Psychiatry at Georgetown University Hospital where he teaches psychoendocrinology. He is founder of the National Center for Whole Psychiatry and is board certified by the American Board of Psychiatry and Neurology, the American Board of Adolescent Psychiatry, and certified as proficient in psychopharmacology by the American Society of Clinical Psychopharmacology. He has been a consultant to the National Institute of Mental Health. Dr. Hedaya obtained both a BA in psychology (Cum Laude, Phi Beta Kappa) and a medical degree at the State University of New York at Buffalo. Subsequently, he acquired specialized training in psychiatry at Georgetown University Hospital's Department of Psychiatry, and at the National Institute of Mental Health. Dr. Hedaya received the Physician's Recognition Award from the American Medical Association each year from 1983 through 1996. In June of 1993, 1997, and 1999, he was voted Outstanding Teacher of the Year by the Geor-

getown University Department of Psychiatry. He has authored *Understanding Biological Psychiatry* (Norton, 1996) and *The Antidepressant Survival Program: How to Beat the Side Effects and Enhance the Benefits of Your Medication* (Crown, 2000).

Mark C. Houston, MD, MSc, SCH, ABAAM, FACP, FAHA, is Clinical Professor of Medicine at Vanderbilt University School of Medicine, and Director of the Hypertension Institute, Vascular Biology and the Life Extension Institute, Saint Thomas Hospital in Nashville, TN. He is also Medical Director of Clinical Research, Section Chief of the Division of Nutrition, and Director of CME in the Hypertension Institute. Dr. Houston graduated from Vanderbilt Medical School, completed his medical internship and residency at the University of California, San Francisco, then returned to Vanderbilt Medical Center as chief resident in medicine. He is certified by the American Board of Internal Medicine; the American Society of Hypertension as a specialist in clinical hypertension (SCH); and the American Board of Anti-Aging Medicine (ABAAM). He completed a Master of Science degree in clinical human nutrition from the University of Bridgeport, Connecticut. He is Editor-in-Chief for the *Journal of the American Nutraceutical Association* (JANA), has published more than 120 articles and scientific abstracts, and completed over 70 clinical research studies. He co-authored the *Handbook of Anti-hypertensive Therapy* (Hanley and Belfus Inc., 2000), *Vascular Biology in Clinical Practice* (Hanley and Belfus Inc., 2002), and *What Your Doctor May Not Tell You about Hypertension* (Warner Books, 2003).

Mark A. Hyman, MD, is Editor-in-Chief of *Alternative Therapies in Health and Medicine*. For nearly 10 years he was Co-Medical Director at Canyon Ranch in the Berkshires, an internationally acclaimed health resort, which is an affiliated practice with Harvard University's Brigham and Women's Hospital. He graduated with a BA from Cornell University in 1982 and Magna Cum Laude from the University of Ottawa School of Medicine in 1987 and from the University of San Francisco's program in family medicine at Community Hospital of Santa Rosa. He is board certified in family medicine. He recently testified at the White House Commission on Complementary and Alternative Medicine Policy on health promotion and wellness, and met with and advised the Surgeon General on a new diabetes prevention initiative. He is on the editorial board of *Integrative Medicine: A Clinician's Journal*. Dr. Hyman combines the

best of conventional and alternative medicine with a blend of science, integrity, intuition and compassion. He is co-author of *Ultraprevention, the 6-Week Plan that Will Make You Healthy for Life* (Scribner, 2003), and *The Detox Box, a Program for Greater Health and Vitality* (Sounds True, 2004). He serves on the Board of Directors for The Institute for Functional Medicine.

Mary James, ND, is a 1985 graduate of the National College of Naturopathic Medicine in Portland, Oregon. Dr. James was in private practice for several years in Portland, represented a nutraceutical company in the northeast, and has worked in medical education at Great Smokies Diagnostic Laboratory in Asheville, NC for more than 10 years. She has lectured widely within the U.S. and abroad, provided ongoing technical support to physicians, developed products, and authored an extensive array of therapeutic guides and technical articles, particularly in the areas of endocrinology and genomics. Dr. James is a member of the American Association of Naturopathic Physicians and serves on the Editorial Review Board of the *Alternative Medicine Review*.

David Jones, MD, is President of The Institute for Functional Medicine. He has practiced as a family physician with emphasis in functional and integrative medicine for over 25 years. He is a recognized expert in the areas of nutrition, lifestyle changes for optimal health, and managed care, as well as the daily professional functions consistent with the modern specialty of Family Practice. Dr. Jones is the recipient of the 1997 Linus Pauling Award in Functional Medicine. He is also the Past President of PrimeCare, the Independent Physician Association of Southern Oregon (IPASO) representing the majority of physicians in the Southern Oregon area. He is author of *Healthy Changes: Taking Charge of Your Health* (HealthComm, 1996).

Joseph J. Lamb, MD, is board certified in both internal medicine and holistic medicine. He is president of the Integrative Medicine Works in Alexandria, Virginia, and is an Assistant Clinical Professor of Medicine at George Washington University School of Medicine. Dr. Lamb works in partnership with his patients to create optimal health and well-being by using functional medical approaches including lifestyle modification, herbal and nutritional therapies, and cognitive therapy. He completed his graduate education at the Medical College of Virginia in Richmond and his residency at Presbyterian University of Pennsylvania Medical Center in Philadelphia. Dr. Lamb, a native Alexandrian, is active

in his community. He is the Past President of the St. Stephen's & St. Agnes Alumni Association and the school physician at Episcopal High School in Alexandria. He is also the president of the Commonwealth Consultants Foundation, a local charity chartered to provide unique educational and social experiences for economically deserving children and young adults.

Robert H. Lerman, MD, PhD, is Medical Director of MetaProteomics, Inc., a subsidiary of Metagenics, Inc., with major emphasis on clinical research at the Functional Medicine Research Center. Previously, he was Senior Medical Advisor and Director of Medical Education for IFM, Director of Clinical Nutrition at Boston Medical Center, and Clinical Associate Professor of Medicine at Boston University School of Medicine. Dr. Lerman is board certified in internal medicine and completed fellowships in nephrology and clinical nutrition. He received his MD degree from Jefferson Medical College and a PhD in nutritional biochemistry from M.I.T. He completed a rotating internship at Letterman Army Medical Center in San Francisco and an internal medicine residency at Tripler Army Medical Center in Honolulu, and attained the rank of major in the U.S. Army Medical Corps. He was Chief of Medicine at U.S. Army Hospitals in Berlin, Germany and Vicenza, Italy and Acting Chief of Nephrology at Soroka Medical Center in Beer Sheva, Israel. He has authored and co-authored numerous papers and book chapters in addition to lecturing widely.

Edward Leyton, MD, CCFP, received his BSc (Hons.) in Biochemistry from the University of Western Ontario in 1970, and subsequently his MD degree in 1975. Since then he has trained in acupuncture with the Canadian Acupuncture Foundation (1979); gestalt therapy with the Gestalt Institute of Toronto (1976); and has followed the concepts of functional nutritional medicine as taught by Dr. Jeffrey Bland since 1982. More recently, Dr. Leyton has attained a master practitioner level in Neuro-Linguistic Programming (NLP) and is a certified hypnotherapist. He was an adjunct faculty member with The Institute of Functional Medicine, where he taught in the Applying Functional Medicine in Clinical Practice course. He is an adjunct academic staff member in the Department of Family Medicine, Queens University, Kingston, Ontario, an award recipient, and published author.

Peter Libby, MD, is the Chief of Cardiovascular Medicine at Brigham and Women's Hospital, Boston, MA, and Mallinckrodt Professor of Medicine at Harvard

Medical School. He directs the D.W. Reynolds Cardiovascular Clinical Research Center at Harvard. Dr. Libby's research currently focuses on the role of inflammation in vascular diseases such as atherosclerosis. His clinical expertise includes general and preventive cardiology, and he has published extensively in medical journals. An editor of Braunwald's *Heart Disease*, he also contributed two chapters on atherosclerosis to Harrison's *Principles of Internal Medicine*. He has held numerous visiting professorships and has delivered over 40 named or keynote lectures. Dr. Libby is a member of the Association of American Physicians and the American Society for Clinical Investigation. An active member of the American Heart Association, he has served on its Executive Committees of the Councils on Arteriosclerosis, Circulation, and Basic Science. He consults frequently to the National Heart, Lung and Blood Institute, and also served a five-year term on the Board of Scientific Counselors. Dr. Libby earned his medical degree at University of California-San Diego, and completed his training in internal medicine and cardiology at the Peter Bent Brigham Hospital.

DeAnn Liska, PhD, is Director of Technical Information and Scientific Publications at Metagenics' Functional Medicine Research Center. She received her PhD in Biochemistry from the University of Wisconsin-Madison in 1987, where she performed her graduate thesis studies on several aspects of vitamin K biochemistry. She also did postgraduate studies in the Department of Biochemistry at the University of Washington as Senior Fellow and, subsequently, Research Assistant Professor, on the subject of nutrient and growth factor effects on gene expression. Dr. Liska has authored numerous papers in peer-reviewed journals, contributed to textbooks on nutrition, is on the Biotechnology and Biomedical Device Advisory Board for the Washington Technology Center. She holds four U.S. patents. Dr. Liska has been an invited speaker at national and scientific meetings, Chair of the Nutrition Division and a member of the Scientific Advisory Panel for the American Association of Cereal Chemists (AACC). She is a member of the National Science Teachers Association and the American Medical Writers Association and serves on IFM's CME Advisory Committee.

Jay Lombard, MD, is an Assistant Clinical Professor of Neurology at Cornell Medical School and Director of the Brain Behavior Center in Pomona, NY. He specializes in Behavioral Neurology including Alzheimer's and

other dementias, autism, Asperger's syndrome and ADHD. His research involves brain imaging and neuropsychopharmacology. Dr. Lombard has published several books including *The Brain Wellness Plan* (Kensington Press, 2000) and *Balance Your Brain* (Wiley, 2004), as well as numerous articles on topics related to brain health. Recently, Dr. Lombard was the medical consultant in the film, *Manchurian Candidate*, starring Denzel Washington and Meryl Streep.

Dan Lukaczer, ND, received his undergraduate degree from Duke University in 1980 and his doctorate in naturopathic medicine from Bastyr University in 1991. From 1991 to 1995, he developed and maintained a private practice. In 1996, he became Director of Clinical Research for the Functional Medicine Research Center, a division of Metagenics, Inc., and served in that capacity until 2005. He is currently working as a senior research scientist for SaluGenecists Inc., a company that is developing evidence-based expert logic health diagnostic systems using advanced computer-based technology. Dr. Lukaczer has taught, lectured and written extensively on botanical and nutritional medicine. He is a core faculty member of The Institute for Functional Medicine and serves on IFM's CME Advisory Committee.

Michael D. Lumpkin, PhD, is a tenured Professor and Chairman of the Department of Physiology and Biophysics at Georgetown University School of Medicine. He earned his doctoral degree in physiology in 1981 from the University of Texas Southwestern Medical School in Dallas. He completed NIH-sponsored post-doctoral fellowship training in neuroendocrinology at Southwestern Medical Center in 1983. Dr. Lumpkin's current research involves studying the stress-related mechanisms by which HIV/AIDS disrupts the neuroendocrine systems that regulate growth, immunity, and reproduction. From this work, he and his research group have produced a patent for treating AIDS-related wasting syndromes in adults and children. He is also a central participant in a large NIH-funded initiative to bring integrative medicine research and education to medical and graduate students at Georgetown. Dr. Lumpkin lectures extensively on the subjects of stress physiology and psychoneuroimmunology. He is an officer in two international scientific societies and serves on several boards of medical foundations. He lectures, instructs and facilitates groups in all aspects of neuroendocrinology, psychoneuroimmunology and mind-body medicine. He is a representative to the

Consortium of Academic Health Centers for Integrative Medicine. Dr. Lumpkin is the author of 180 scientific articles, book chapters, and abstracts.

Michael Lyon, BSc, MD, is Medical and Research Director for the Canadian Center for Functional Medicine located in Coquitlam, BC. He heads up a team of clinicians and researchers dedicated to biotechnology and natural health product research. He is involved in collaborative clinical research with the University of Toronto and the Imperial College of Medicine in London, England in the field of obesity, diabetes, and appetite regulation; and with the University of British Columbia in the area of childhood learning and behavioral disorders. Dr. Lyon served as an Olympics team physician (1988-1992) and was also head of a National Sport Science Committee for Sport Canada. He has a long-standing interest in toxicology and he has lectured frequently on the subject. He is the author of *Healing the Hyperactive Brain through the New Science of Functional Medicine* (Focused Publishing, 2000), and co-author of *Is Your Child's Brain Starving?* (Mind Publishing, 2002), and *How to Prevent and Treat Diabetes with Natural Medicine* (Riverhead Books, 2003).

Woody R. McGinnis, MD, was educated at Dartmouth College and the University of Colorado. After volunteer medical work in rural Peru, he practiced general medicine in Arizona for many years. In 1993, Dr. McGinnis began studying nutritional influences on behavior. Nutritional treatment of autism and other behavioral disorders became the primary focus of his practice. In 2001, Dr. McGinnis committed to full-time research in behavioral nutrition. He initiated and coordinates the Oxidative Stress in Autism Study, a first-of-its-kind university collaboration measuring a broad range of oxidative markers in the urine, blood, and central nervous system of children with autism. The urinary Mauve Factor is an area of special interest for McGinnis, who proposes that Mauve is a biomarker for oxidative stress. He resides in Ashland, Oregon, with his wife, Julia, and two sons. To balance his work, he reads, plays frisbee, does yoga, picks blueberries and generally strives to exemplify a healthful, low-oxidizing lifestyle.

Carolyn McMakin, MA, DC, is the clinical director of Integrated Pain Solutions and the Fibromyalgia and Myofascial Pain Clinic in Portland, Oregon. In addition to maintaining an active clinical practice, she teaches seminars on the use of Frequency Specific Microcurrent. She has lectured at the National Institutes of Health and

at numerous conferences in the U.S., England, Canada and Australia on the subjects of fibromyalgia, and fibromyalgia associated with cervical trauma; and on the differential diagnosis and treatment of pain and pain syndromes, and sports injuries.

David Musnick, MD, is board certified in internal medicine and sports medicine with 16 years of experience. He practices in Bellevue, Washington at the Comprehensive Medical Center, an integrative medical center. His practice focuses on orthopedic and sports medicine, pain management, and functional internal medicine. An expert in exercise prescription, Dr. Musnick is the author of *Conditioning for Outdoor Fitness: Functional Exercise and Nutrition for Every Body* (The Mountaineers Books, 2004). He teaches seminars on Exercise Prescription, Orthopedic Medicine and Pain Management. Dr. Musnick is on the faculty at the University of Washington, Dept. of Sports Medicine and Orthopedics, and was the instructor of Orthopedic Medicine and Sports Medicine for five years at Bastyr University. He serves on the CME Advisory Committee for The Institute for Functional Medicine.

Joseph E. Pizzorno Jr., ND, is a leading authority on science-based natural medicine. A physician, educator, researcher, and expert spokesperson, Dr. Pizzorno was the Founding President (now Emeritus) of Bastyr University. He is also President of SaluGenecists, Inc. In 1996, he was appointed to the Seattle/King County Board of Health and the founding board of directors of the American Herbal Pharmacopoeia. In 2002, he became the founding editor of *Integrative Medicine: A Clinician's Journal*. Dr. Pizzorno was appointed by President Clinton in December 2000 to the White House Commission on Complementary and Alternative Medicine Policy and, in November 2002, was appointed by President Bush's administration to the Medicare Coverage Advisory Committee. In 2002, he was awarded "Naturopathic Physician of the Year" by the American Association of Naturopathic Physicians; in 2003, the American Holistic Medical Association recognized him as a "Pioneer in Holistic Medicine"; and in 2004, The Institute for Functional Medicine honored him with the Linus Pauling Award. Dr. Pizzorno is the author of *Total Wellness* and co-author of *A Textbook of Natural Medicine, Handbook of Natural Medicine, Encyclopedia of Natural Medicine, Natural Medicine for the Prevention and Treatment of Cancer*, and *The Encyclopedia of Healing Foods* (Atria Books, 2005).

Lara Pizzorno, MA Div, MA Lit, LMT, was among the first 10 women to graduate from Yale Divinity School with a Masters in Divinity in 1973. She earned her second Masters in Literature from the University of Washington and is also a Licensed Massage Therapist. A member of the American Medical Writers Association with more than 25 years of experience writing and editing articles, books, and website content for physicians and the public, Lara is employed as Senior Medical Editor for SaluGenecists, Inc., in Seattle. Her favorite responsibility is reviewing and summarizing the nutrition-related research each month to update The World's Healthiest Foods, a non-profit website created by SaluGenecists for the George Mateljan Foundation. Lara has attended all but one of the IFM symposia and is an AFMCP graduate. She is a contributing author to the *Textbook of Natural Medicine* (Churchill Livingstone, 3rd ed. 2005), lead author of *Natural Medicine Instructions for Patients* (Churchill Livingstone, 2002), and a co-author of *The Encyclopedia of Healing Foods* (Atria Books, 2005).

James O. Prochaska, PhD, is Director of the Cancer Prevention Research Center and Professor of Clinical and Health Psychology at the University of Rhode Island. He is the author of over 250 publications, including three books, *Changing for Good*, *Systems of Psychotherapy* and *The Transtheoretical Approach*. He is internationally recognized for this work as a developer of the stage model of behavior change. He is the principal investigator for over \$70 million in research grants for the prevention of cancer and other chronic diseases. Dr. Prochaska has won numerous awards including the Top Five Most Cited Authors in Psychology from the American Psychology Society; an Innovator's Award from the Robert Wood Johnson Foundation and he is the first psychologist to win a Medal of Honor for Clinical Research from the American Cancer Society.

Janice M. Prochaska, MSW, PhD, is President and CEO of Pro-Change Behavior Systems, Inc. and an adjunct professor in the Department of Human Development and Family Studies at the University of Rhode Island. Her business is dedicated to the scientific development and dissemination of Transtheoretical Model-based change management programs. Through Small Business Innovation research grants from the National Institutes of Health, her company's LifeStyle management programs for depression management, regular exercise, stress management, and weight management are being disseminated through health insurance com-

panies and employers. In addition, through an alliance with the Channing Bete Company, Pro-Change is developing effectiveness tested programs for elementary, middle, and high schools that include obesity prevention, bullying prevention, and substance abuse prevention.

Sheila Quinn, BS, has worked in health-related non-profit organizations for more than 30 years, and in the healthcare arena itself for more than 45 years. Following twelve years as Co-founder and Vice President at Bastyr University and seven years as Executive Director of the American Association of Naturopathic Physicians, she became Senior Editor at IFM in late 2000. She has co-authored and edited many reports and publications, and was Managing Editor for IFM's *Clinical Nutrition: A Functional Approach*, 2nd edition (2004). She helped to organize the Seattle Town Hall Meeting for the White House Commission on CAM Policy in October 2000. She served on the Steering Committee for the 2001 *National Policy Dialogue to Advance Integrated Health Care: Finding Common Ground* (and co-edited the final report). She is currently Board Chair and member of both the Executive Committee and the Education Task Force for the Integrated Healthcare Policy Consortium. Through her decades of work both inside and outside the healthcare mainstream, she has become knowledgeable about health-related public policy issues and is committed to helping create a safe and effective integrated healthcare system. She attended Reed College, Stanford University, and received a BS in accounting from City University.

Robert Rountree, MD, received his medical degree from the University of North Carolina School of Medicine at Chapel Hill in 1980. He subsequently completed a residency in family and community medicine at the Milton S. Hershey Medical Center in Hershey, PA, after which he was certified by the American Board of Family Practice. He is a diplomate of the American Board of Holistic Medicine and has augmented his training with postgraduate studies in nutritional and herbal pharmacology and certification as a master practitioner of Neuro-Linguistic Programming. Dr. Rountree has provided his unique combination of traditional family medicine, nutrition, herbology, and mind-body therapy in Boulder, CO since 1983. He is co-author of three books on Integrative Medicine, *Immunotics: A Revolutionary Way to Fight Infection, Beat Chronic Illness and Stay Well* (Putnam, 2000), *Smart Medicine for a Healthier Child* (Avery Publishing, 1994) and *A Parent's Guide to Medical Emergencies* (Avery, 1997). Dr. Rountree is an adjunct faculty

member at The Institute for Functional Medicine, and serves on the advisory board for the Herb Research Foundation and on the editorial boards of *The Journal of Alternative and Complementary Medicine*, *Alternative and Complementary Therapies*, and *Delicious! Living Magazine*.

Barb Schiltz, RN, MS, CN, has been a registered nurse for 40 years with an undergraduate degree in Foods and Nutrition and a Master's Degree in Nutrition from Bastyr University. Since 1996, she has been working as a nutrition consultant and research nurse at The Functional Medicine Research Center (FMRC) in Gig Harbor, WA, monitoring patients undergoing clinical trials for irritable bowel disease, fibromyalgia, diabetes, ADHD, and PMS. Her passion was expressed in her Master's Thesis, *The Unique Role of Carbohydrate Metabolism in Regulation of Glycemic Index*.

Virginia Shapiro, DC, DACBN, has practiced functional medicine as a chiropractor since 1985. She earned her bachelor's degree in biology at Carleton College in 1977, and her doctor of chiropractic degree at Northwestern University of Health Sciences in Minneapolis in 1985. In 1996 she completed her board certification in clinical nutrition by the American Chiropractic Board of Clinical Nutrition. A student of clinical nutrition and natural health care approaches, she has continued intensive postgraduate studies with a number of the most prominent holistic practitioners in the U.S. and the U.K. She has lectured to clinicians regarding clinical nutrition, essential fatty acid biology, nutrition in cardiovascular health, nutrition in mood and behavioral disorders, and applying functional medicine to women's hormonal health. Her successful functional medicine practice, Northland Health and Wellness in Duluth, Minnesota, provides comprehensive medical, nutritional, and chiropractic services in a joyful, compassionate, and healing environment.

Michael Stone, MD, MS, is a board certified family physician who practices in Ashland, Oregon with Leslie Stone, MD, and David Jones, MD. He has experience in rural and frontier family medicine, emergency medicine, and as a hospitalist. His undergraduate and graduate degrees are in human nutrition. He graduated from the University of Washington, and did his residency training in family practice at UCLA-Ventura, where he was chief resident, and also completed a teaching fellowship in family medicine. Dr. Stone has been an adjunct faculty at UCLA and University of Washington for primary care students in the Doctoring and RUOP

programs. His career has offered him medical experiences and practice in Thailand, Alaska, eastern Sierras, Idaho, and Oregon. His interests and lectures have covered a wide range of topics, including bezoars to neonatal hypocalcemia, health issues with depleted uranium, exposure to Vitamin D and chronic disease.

Nancy Sudak, MD, completed her medical education at Case Western Reserve University in 1989, and received her residency training in family practice in Duluth, Minnesota in 1992. Board certified in both family practice and holistic medicine, she is currently in private practice in an integrated chiropractic-medical clinic in Duluth. She is a clinical instructor for the University of Minnesota School of Medicine, an active board member of the American Board of Holistic Medicine, and an editorial board member for *Integrative Medicine: A Clinician's Journal*. She attended the inaugural Applying Functional Medicine in Clinical Practice course by The Institute for Functional Medicine in 1998, which facilitated a comprehensive revitalization of her practice. She is an enthusiastic community speaker on various health-related topics.

Thomas Sult, MD, practices family and functional medicine in St. Cloud, MN. He utilizes a full range of diagnostic and therapeutic interventions ranging from ultra-fast CT and genomic testing, to lifestyle counseling and meditation. Dr. Sult is an Assistant Clinical Professor of Medicine at the Department of Family and Community Medicine, University of MN, and an instructor for the Rural Health School of Medicine, a cooperative educational outreach program of the University of MN. He is also the Medical Director of A Chance to Grow, a multidisciplinary rehabilitation clinic for brain-injured children, in Minneapolis. Dr. Sult is board certified in family medicine and holistic medicine. He is a Fellow of the American Academy of Family Medicine and a graduate of Applying Functional Medicine in Clinical Practice. While spending two years at St. Georges School of Medicine in Grenada, West Indies, he was introduced to the herbal and shamanistic customs of the Grenadian "bush doctor." Upon transfer to UCLA School of Medicine, Dr. Sult was introduced to Dr. Norman Cousins and the Division of Psychoneuroimmunology. Dr. Cousins became a close mentor to Dr. Sult and helped him form an understanding of the healing techniques he had witnessed in Grenada.

John M. Tatum, MD, is Founder and Medical Director of Optimal Health & Learning Center in Winter Park,

Florida. Dr. Tatum completed his medical degree at the Medical College of Georgia and his specialty training in psychiatry at the Shepard and Enoch Pratt Hospital in Baltimore, MD. He specializes in functional medicine, wellness, psychiatry, psychotherapy, microcurrent therapy, ADHD, learning disabilities, relationship therapy, and personal growth. He uses quantitative electroencephalograms, neurofeedback, and Tomatis Listening Therapy. He was the first to introduce and write about the synergy of combining Tomatis sound stimulation with simultaneous learning disability remediation. Although the field of psychotherapy focuses mostly on cognitive behavioral therapy, Dr. Tatum believes it is what is programmed into the deeper unconscious that causes most people their repetitive psychological problems, and this can be accessed through the body's subtle energy system. He has developed techniques for integrating bioenergetics into psychotherapy and has written and lectured on this at a national level. By using this multimodality approach and allying with the body's powerful forces for healing and growth, people can achieve levels of healing and growth not possible with a medication-only model.

Alex Vasquez, DC, ND, completed his undergraduate work in human biology by studying disorders of iron metabolism, and later published some of his findings in *Nutritional Perspectives* and *Arthritis & Rheumatism*. He graduated from Western States Chiropractic College with his Doctor of Chiropractic degree before attending Bastyr University, where he received his Doctor of Naturopathic Medicine degree. While maintaining a private practice in Seattle, Dr. Vasquez served as Adjunct Professor of Orthopedics, Rheumatology, and Radiographic Interpretation at Bastyr University, and he began work on his 486-page textbook, *Integrative Orthopedics: The Art of Creating Wellness While Effectively Managing Musculoskeletal Disorders* (Natural Health Consulting Corp., 2004). Dr. Vasquez has lectured nationally and internationally to professional audiences, and his articles and letters have been published by *Journal of the American Medical Association*, *British Medical Journal*, *The Lancet*, *Alternative Therapies in Health and Medicine*, and many other peer-reviewed medical journals.

David Wickes, DC, is Executive Vice President and Provost at the Western States Chiropractic College in Portland, Oregon. He graduated in 1977 from the National College of Chiropractic (NCC) and completed a two-year residency in chiropractic family practice. He

chaired the Department of Diagnosis at NCC from 1980-1991, then he subsequently served as the Director of the Inpatient Facility, the Director of the Training and Assessment Center, the Dean of Clinics, the Vice President for Academic Affairs, and the Senior Vice President and Provost. He is board certified in diagnosis and internal disorders, and has been an adjunct faculty member of The Institute for Functional Medicine. He has lectured nationally and internationally on the diagnosis and management of chronic disorders.

Catherine Willner, MD, is a practicing neurologist in Durango, Colorado. She received her formal training in Neurology at the Mayo Clinic including subspecialty training in autonomic, peripheral neurology as well as pain management. She remained on staff at the Mayo Clinic until 1997, at which time she relocated to Colorado to focus her practice on functional neurology. She is board certified in neurology and in pain management. Prior to pursuing her MD degree, Dr. Willner was enrolled briefly in the National College of Naturopathic Medicine when the program was in Kansas. Her interest in biochemical individuality, nutritional biochemistry and functional medicine, though somewhat on hold during the Mayo years, is currently thriving in Durango. She is an adjunct faculty member of The Institute for Functional Medicine, and created a clinical module in Functional Neurology for IFM.

2010 Edition Update

Kara N. Fitzgerald, ND, received her doctorate in naturopathic medicine from National College of Naturopathic Medicine in Portland, Oregon. She completed CNME-accredited postdoctoral training in laboratory science with concurrent residency training at an integrative medical center in Atlanta, Georgia. Dr. Fitzgerald is a contributing author to *Laboratory Evaluations for Integrative and Functional Medicine* and is co-authoring and editing a book of case studies in integrative medicine. She is adjunct faculty at The Institute for Functional Medicine. She also lectures internationally on the clinical application of functional laboratory interpretation. Dr. Fitzgerald maintains a clinical practice at Advanced Diagnostic, in New Haven, Connecticut.

Comprehensive Elimination Diet—Sample Patient Handouts

Introduction

The Comprehensive Elimination Diet is a dietary program designed to clear the body of foods and chemicals you may be allergic or sensitive to, and, at the same time, improve your body's ability to handle and dispose of these substances.

We have called this an "Elimination Diet" because we will be asking you to remove certain foods, and food categories, from your diet. The main rationale behind the diet is that these modifications allow your body's detoxification machinery, which may be overburdened or compromised, to recover and begin to function efficiently again. The dietary changes help the body eliminate or "clear" various toxins that may have accumulated due to environmental exposure, foods, beverages, drugs, alcohol, or cigarette smoking.

In our experience, this process is generally well tolerated and extremely beneficial. We obviously hope that you will find it useful too. There is really no "typical" or "normal" response. A person's initial response to any new diet is highly variable, and this diet is no exception. This can be attributed to physiological, mental, and biochemical differences among individuals; the degree of exposure to, and type of "toxin"; and other lifestyle factors. Most often, individuals on the elimination diet report increased energy, mental alertness, decrease in muscle or joint pain, and a general sense of improved well-being. However, some people report initial reactions to the diet, especially in the first week, as their bodies adjust to a different dietary program. Symptoms you may experience in the first week or so can include changes in sleep patterns, lightheadedness, headaches, joint or muscle stiffness, and changes in gastrointestinal function. Such symptoms rarely last for more than a few days.

We realize that changing food habits can be a complex, difficult and sometimes confusing process. It doesn't have to be, and we think that we have simplified the process with information to make it a "do-able" process. Peruse this information carefully.

Bon appétit!

Guidelines

A 7-Day Menu Plan (including recipes) and three tables are included with these materials:

- Table 1—Foods to Include and Exclude. Eat only the foods listed under "Foods to Include," and avoid those foods shown under "Foods to Exclude." If you have a question about a particular food, check to see if it is on the food list. You should, of course, avoid any foods (listed or not) to which you know you are intolerant or allergic. Some of these guidelines may change based upon your personal health condition and history.
- Table 2—Shopping List
- Table 3—Food Reintroduction Chart

A few suggestions that may be of help:

- You may use leftovers for the next day's meal or part of a meal, e.g., leftover broiled salmon and broccoli from dinner as part of a large salad for lunch the next day.
- It may be helpful to cook extra chicken, sweet potatoes, rice, and beans, etc. that can be reheated for snacking or another meal.
- If you are consuming coffee or other caffeine-containing beverages on a regular basis, it is always wise to slowly reduce your caffeine intake rather than abruptly stop it; this will prevent caffeine-withdrawal headaches. For instance, try drinking half decaf/half regular coffee for a few days, then slowly reduce the total amount of coffee.
- Select fresh foods whenever you can. If possible, choose organically grown fruits and vegetables to eliminate pesticide and chemical residue consumption. Wash fruits and vegetables thoroughly.
- Read oil labels; use only those that are obtained by a "cold pressed" method.
- If you select animal sources of protein, look for free-range or organically raised chicken, turkey, or lamb. Trim visible fat and prepare by broiling, baking, stewing, grilling, or stir-frying. Cold-water fish (e.g., salmon, mackerel, and halibut) is another excellent source of protein and the omega-3 essential fatty acids, which are important nutrients in this diet.

- Remember to drink at least two quarts of plain, filtered water each day.
- Strenuous or prolonged exercise may be reduced during portions of this program (or even during the entire program) to allow the body to heal more effectively without the additional burden imposed by exercise. Adequate rest and stress reduction are also important to the success of this program.

Finally, anytime you change your diet significantly, you may experience such symptoms as fatigue, headache, or muscle aches for a few days. Your body needs time as it is “withdrawing” from the foods you eat on a daily basis. Your body may crave some foods it is used to consuming. **Persevere.** Those symptoms generally don’t last long, and most people feel much better over the next couple of weeks.

7-Day Menu Plan

This suggested day-by-day menu that can be followed for one week while on the Comprehensive Elimination Diet is intended only as a sample; it can be modified according to the patient's preferences. Serving sizes in each recipe are approximate and can be adapted to the patient's appetite. Foods from different days may be mixed and matched differently, according to the patient's preferences.

Substitutions are allowed as long as restricted foods are avoided. For example, many instant or canned soups from the health food store are acceptable, but all labels must be read to be sure.

DAY 1

Breakfast

Cooked whole grain cereal (oatmeal, cream of brown rice, buckwheat, teff, or quinoa flakes)

- served with rice, oat, or almond milk, cinnamon, and allowable sweetener of your choice
- garnished with chopped walnuts, almonds, hazelnuts, or toasted pumpkin seeds
- topped with fresh or frozen unsweetened fruit

Lunch

Lentil soup or split pea soup or black bean soup
Sesame rice crackers or rice cakes
Carrot and celery sticks
Fresh figs, plums, or cherries

Dinner

Broiled salmon
Cooked millet or baked white or sweet potato or quinoa salad
Oven-roasted veggies
Mixed green salad with vinaigrette dressing
Crispy rice squares or fresh apple

DAY 2

Breakfast

Fruit Smoothie:

- blend rice or almond milk with ½ banana and/or pineapple slice and one or two ice cubes
- add flax powder or other fiber if desired

Applesauce bread or banana bread

Lunch

Asparagus soup (or yesterday's leftover soup)
Cabbage salad
Rice cakes with walnut butter
Fresh peach or pear

Dinner

Broiled lamb chop
Nutty green rice or mock mac'n cheese
Cooked veggie mix:

- steam broccoli, cauliflower, and carrots
- toss with olive oil and herbs (oregano, thyme, basil, tarragon, etc.)

Fruity spinach salad

DAY 3

Breakfast

Nutri-Ola or crispy brown rice or puffed rice or puffed millet cereal

- served with rice or almond milk, topped with sliced berries

Leftover applesauce bread or banana bread

Lunch

Brown rice and black beans mix

- topped with flax oil
- garnished with chopped scallions and sliced avocado or guacamole

Baking powder biscuits
Tropical fruit salad

- sliced mango, kiwi, and strawberries
- topped with shredded unsweetened coconut and chopped walnuts or pecans

Dinner

Broiled or poached halibut
Baked butternut or acorn squash, sprinkled with cinnamon
Chopped zucchini, red peppers, garlic, and onion sautéed in olive oil, topped with basil
Mixed green salad with vinaigrette dressing

- choose greens from arugula, endive, radicchio, red leaf, romaine, butter head, Boston, cabbage, dandelion, escarole; add red cabbage, garbanzo beans, red onion, olives, carrots

Mochi rice squares and fresh fruit

DAY 4

Breakfast

Sweet potato delight and/or leftover Nutri-Ola square
Cantaloupe half, filled with blueberries and sprinkled with cinnamon

Lunch

Leftover brown rice and black beans mix or
Halibut salad:

- Mixed greens of your choice
- chopped vegetables with garbanzo or kidney beans
- leftover halibut cut into chunks
- vinaigrette dressing

Fresh banana or leftover crispy rice squares

Dinner

Skinless chicken, oven baked or broiled, sprinkled with garlic powder and tarragon
 Brown rice or wild rice, or basic kasha, dressed with flax or sesame oil
 Asparagus, cut into 1-inch pieces and stir-fried in olive oil and garlic
 Gingerbread

DAY 5**Breakfast**

Mochi rice waffles, topped with sautéed apples
 Fruit smoothie:

- blend rice or almond milk with a peach and/or raspberries and one or two ice cubes
- add flax powder or other fiber if desired

Lunch

Quinoa salad or

Chicken salad:

- mixed greens
- leftover chicken, cut into pieces
- your choice of guacamole or nutty mayo

Beans and greens soup

Rice cakes or rice bread with pear honey or unsweetened apple butter

Dinner

Fresh tuna, topped with herbs (tarragon, dill, or parsley), and broiled

Rice pasta with olive oil and mock pesto or baked sweet potato topped with flax oil

Steamed vegetables: kale or collard greens tossed with olive oil and garlic

Mixed green salad with kidney beans and vinaigrette dressing

Fresh fruit salad: mango and pineapple chunks, sliced kiwi

DAY 6**Breakfast**

Meal in a muffin or breakfast rice pudding

Rice milk, oat milk, or almond milk; berries, sweetener, and pecans

Lunch

Tuna salad:

- leftover tuna, mashed and mixed with:
- hummus (made with only natural food ingredients)

Leftover beans and greens soup

Baking powder biscuits

Fresh pear or nectarine

Dinner

Roast turkey breast or broiled turkey burger or spiced lentil casserole

Brown rice and peas

Steamed broccoli, carrots, and/or green beans topped with flax oil and herbs of choice

Baked apple

DAY 7**Breakfast**

Toasted rice bread topped with pear butter or

Rice pancakes topped with pear butter or sautéed apples

Cantaloupe chunks

Lunch

Turkey salad:

- Mixed greens or mix of cannellini beans, celery, scallions, and apple chunks,
- Nutty mayo or hummus

Cucumber slices marinated in rice vinegar and dill

Rice crackers

Banana

Dinner

Rice pasta primavera or black beans and yellow rice

Pickled beets

Mixed green salad with cherry tomatoes and vinaigrette dressing

Leftover breakfast rice pudding topped with dried apples

Snack Suggestions

Rice cakes or rice crackers spread with:

- almond or cashew nut butter or
- apple butter or
- pear honey

Sesame rice crackers and hummus

Fresh fruits (except orange)

Fresh raw veggie wedges

Nuts and seeds (except peanuts)

Crispy rice squares, gingerbread

Mochi rice squares, plain, with smashed berries or nut butters

Sparkling mineral water or seltzer with unsweetened fruit juice

Recipes for 7-Day Menu (in alphabetical order)

Applesauce Bread—Yields 14 slices

1 cup teff flour
1 cup oat or rice flour
1 tsp. baking soda
½ tsp. cinnamon
¼ tsp. salt
¼ tsp. nutmeg
1 cup unsweetened applesauce
1 tbsp. safflower or sesame oil
½ cup brown rice syrup or fruit juice concentrate
egg replacer to equal 1 egg (recipe under Baking Tips)
3–4 tbsp. apple butter
1 tsp. pure vanilla extract

Combine the dry ingredients in a large bowl. Combine the wet ingredients in a small bowl and mix into the dry ingredients. Pour into oiled 9-inch square pan. Bake at 350 degrees for 30 minutes.

Asparagus Soup—Serves 4

Used with permission from "The Allergy Self Help Cookbook," by Marjorie Hurt Jones, R.N. Rodale Press, Emmaus, Pa.

1 lb. asparagus, trimmed
2 medium leeks or 4 large shallots
1 tbsp. oil
2–3 cloves garlic, minced
2 cups water, vegetable, or chicken stock (or a combination)
1 tsp. dried dill weed
pinch nutmeg

Slice off the tips of the asparagus and reserve them. Cut the remaining stalks into 1" pieces. Slice the leeks in half lengthwise and wash under cold water to remove any sand. Slice into ¼" pieces. Sauté the leeks or shallots in the oil over medium heat until soft. Add the garlic and sliced asparagus stalks. Cook, stirring, another minute or two. Add the water or stock and dill. Simmer 10–12 minutes.

Remove from heat, allow to cool 5–10 minutes. Puree half the volume at a time. Return to pan, add the reserved asparagus tips and simmer 3–5 minutes or until tips are just barely tender. Add nutmeg. If soup is too thick, thin with additional water or stock.

Baked Apple—Serves 6

1/3 cup golden raisins
2 tbsp. apple juice
6 cooking apples, cored
1½ cups water
¼ cup frozen unsweetened apple juice concentrate
2 tsp. pure vanilla extract
1 tsp. cinnamon
1 tsp. arrowroot

Remove peel from top third of each apple and arrange in a small baking dish. In a medium saucepan, combine other ingredients and bring to a boil, stirring frequently. Reduce heat and simmer 2–3 minutes, until slightly thickened. Distribute raisins, filling centers of each apple. Pour sauce over apples and bake, uncovered, at 350 degrees for 1 to 1½ hours. Baste occasionally and remove from oven when apples are pierced easily with a fork. Spoon juice over apples and serve warm.

Baking Powder Biscuits—Makes one dozen

1½ cups brown rice flour
½ cup tapioca flour
4 tsp. baking powder
1/8 tsp. salt
3 tbsp. safflower or sesame oil
1 cup applesauce, unsweetened

Preheat oven to 425 degrees. In a medium-large mixing bowl, stir together dry ingredients. Sprinkle oil on top and mix well with a pastry blender or fork, until consistency is crumbly. Mix in applesauce and stir until blended. Spoon heaping tablespoonfuls onto ungreased cookie sheet. With spoon, lightly shape into biscuit. Bake 15–18 minutes until slightly browned. Serve warm for best flavor, but may be lightly reheated in a microwave.

Banana Bread—Yields 14 slices

¼ cup walnuts, ground finely in blender
1¾ cups brown rice flour
½ cup arrowroot
2 tsp. baking soda
¼ tsp. salt
½ cup chopped walnuts
1½ cups ripe mashed banana
¼ cup safflower or sesame oil
6 tbsp. apple juice concentrate
egg replacer to equal 2 eggs (recipe under Baking Tips)
1 tsp vanilla extract

Preheat oven to 350 degrees. Mix finely ground walnuts with flour, arrowroot, baking soda and salt in a large bowl. Stir in the chopped walnuts. In a separate bowl, mix together the banana, oil, apple juice, egg replacer, lemon and vanilla. Add to the flour mixture and stir until just moistened. Do not overmix. Pour into a greased 9" x 5" loaf pan and bake for 55–60 minutes or until cake tester inserted in middle comes out clean. Cool in pan for 10 minutes, then remove from pan and cool on wire rack.

Basic Kasha—Serves 4–5

1 cup buckwheat groats
2 cups water, chicken or vegetable broth (or a combination)

Roast the dry buckwheat groats over medium heat in a dry skillet, stirring until the grains begin to smell toasty, about 2 minutes. Add the water or broth, cover and simmer for 20–30 minutes, until kasha is tender but not mushy. Pour off any excess liquid. Optional: add onion, garlic and herbs to the dish.

Beans and Greens Soup—Serves 4–5

2 cups cooked white beans
2 tbsp. olive oil
2 medium cloves garlic, crushed
1 large onion, chopped
1 bay leaf
1 stalk celery, diced
2 medium carrots, diced
1 tsp. salt
fresh black pepper
6 cups water, vegetable or chicken broth (or a combination)
½ lb. fresh chopped escarole, spinach, chard, or collards (or a combination)

In a 4–6 quart soup pot, sauté the onions and garlic in olive oil over low heat. When onions are soft, add bay leaf, celery, carrot, salt and pepper. Stir and sauté another 5 minutes. Add broth or water and cover. Simmer about 20 minutes. Add cooked beans and your choice of greens. Cover and continue to simmer, over very low heat, another 15–20 minutes. Serve immediately or refrigerate and reheat.

Black Beans and Yellow Rice—Serves 4**Black Beans**

1 cup dry black beans, soaked overnight and drained
4 cups water
1 small onion, chopped
1 small carrot, chopped
2 cloves garlic, minced
1 bay leaf
1 tsp. cumin

In a 3-quart saucepan, combine beans, water, onion, carrot, garlic, bay leaf, cumin, and pepper flakes. Bring to a boil over medium heat and simmer, uncovered, about 2½ hours, or until beans are tender and almost all liquid is absorbed. Discard bay leaf. (May be made up to 2 days ahead; reheat before serving.)

Yellow Rice

2 cups chicken or vegetable stock
1 small onion, finely chopped
2 tsp. olive oil
1 clove garlic, minced

½ tsp. turmeric
1 cup uncooked long-grain brown rice

In a 2-quart saucepan over low heat, sauté onions in oil until tender, about 5 minutes. Add the garlic and sauté 1 minute. Stir in turmeric, then rice. Add stock. Bring to a boil, cover and simmer 45 minutes over low heat, or until rice is tender and all liquid is absorbed. Do not stir. Spoon beans over rice.

Breakfast Bars

Add egg replacer (recipe under Baking Tips) to equal 2 eggs to Nutri-Ola (recipe below). Slowly add additional water to make a stiff batter. Follow directions for Nutri-Ola, but spread into an 8- or 9-inch square pan (ungreased) and bake at 350 degrees about 30 minutes. Cut into squares when done.

Breakfast Rice Pudding—Serves 4

1 cup uncooked short grain brown rice
1¼ cups coconut milk
1¼ cups water
½ tsp. salt
1 tbsp. brown rice syrup
1 tsp. cinnamon
chopped almonds or sunflower seeds or other nuts of choice or a mixture (optional)

Combine water and coconut milk in heavy pot; bring to boil, adding rice and salt. Simmer, covered (do NOT stir) for about 45 minutes or more, until liquid is mostly absorbed and rice is soft. Remove from heat and allow to cool for 15 minutes. Stir in brown rice syrup and cinnamon and top with nuts or seeds as desired.

Brown Rice and Peas—Serves 4

Add 1 cup of green peas (either fresh and lightly steamed or frozen and just defrosted baby peas) to 2 cups of cooked brown rice. Top with your favorite herbs and flax oil to taste.

Cabbage Salad—Serves 4–6

1 small to medium head red cabbage, thinly sliced (or use half red and half green cabbage)
8 sliced radishes, and/or 1 grated carrot
3 green apples, diced
1 stalk celery, chopped
½ cup chopped walnuts or pecans (or mixture)
dash garlic powder
2 tbsp. olive oil
2 tsp. vinegar
1 tsp. lemon juice

Mix all ingredients in a bowl and allow to rest and blend for an hour, stirring once or twice. Serve cold or at room temperature.

Crispy Rice Squares—2 dozen

1 tsp. cold pressed canola oil
½ cup brown rice syrup
2 tbsp. sesame tahini or almond butter
3 tsp. vanilla extract
2 cups crispy brown rice cereal
2 cups puffed rice
2 cups puffed millet or Perky's Nutty Rice
½ cup pumpkin or sunflower seeds
½ cup currants or chopped dried apple or chopped dates

Heat oil in a large pot; add rice syrup and tahini or almond butter. Stir until bubbly. Remove from heat and stir in vanilla. Add remaining ingredients and mix well with a wooden spoon. Press into an ungreased 13 x 9 pan and press mixture flat. Let mixture rest at room temperature or refrigerate. Cut into squares. Store in an airtight container.

Fruity Spinach Salad—Serves 6–8

1 lb. fresh spinach, washed, dried, torn into pieces
1 pint fresh organic strawberries or raspberries, washed
½ cup chopped walnuts or sliced almonds

Dressing:

2 tbsp. sesame seeds
1 tbsp. poppy seeds
2 scallions, chopped
¼ cup flax seed oil
¼ cup safflower oil
¼ cup balsamic vinegar

Cut berries in half and arrange over spinach in serving bowl. Combine dressing ingredients in blender or food processor and process until smooth. Just before serving, pour over salad and toss. Garnish with nuts.

Gingerbread—9 squares

Adapted with permission from "Gluten-Free, Sugar-Free Cooking" by Susan O'Brien, Da Capo Press, 2006.

½ cup pecans or walnuts, finely chopped
½ cup agave nectar (preferred) or fruit sweetener
¼ cup canola oil
egg replacer to equal 2 eggs (see Baking Tips)
1 tsp vanilla
1½ cups brown rice flour
½ tsp salt
1 tsp baking powder
1 tsp baking soda
2 tsp ginger
1½ tsp cinnamon
¼ tsp nutmeg
1/8 tsp cloves
½ tsp orange rind
1 cup unsweetened applesauce

In a large mixing bowl, combine the agave nectar and oil. Beat on high speed until thoroughly blended. Add in the eggs, one at a time. Be sure to beat well between eggs. Add in the orange rind and vanilla and continue to blend together. Set aside.

Meanwhile, preheat the oven to 350 degrees and spray a 9 x 9 square pan with a nonstick spray. Sift together the dry ingredients and add the nuts. Add some of the dry ingredients to the wet ingredients, a little at a time, blending well. Add in ¼ cup of the applesauce, blend, then add in more flour. Continue this process until you have added all of the ingredients.

Pour the batter into the prepared pan and bake for 20–25 minutes, or until the gingerbread is done. Check for doneness by inserting a toothpick, or touching lightly on the center. Freezes well.

Guacamole—Makes 1½–2 cups

Used with permission from "The Allergy Self Help Cookbook," by Marjorie Hurt Jones, R.N. Rodale Press, Emmaus, Pa.

2–3 ripe avocados
¼ cup chopped onions
¼ tsp. vitamin C crystals
1 tbsp. water
1 small clove garlic, chopped

Cut the avocados in half, remove the pits, then scoop the flesh into a blender or food processor. Add the onions, vitamin C crystals, water, and garlic. Process until smooth. Transfer to a small bowl. Cover and chill. Use within 2–3 days. To prevent darkening, coat top with a thin layer of oil. For a chunky version, mash the avocado with a fork and finely chop onions and garlic.

Lentil Soup—Serves 4

2 cloves garlic, minced
1 medium onion, chopped
2 large carrots, sliced or chopped
2 stalks celery, chopped
1½ cups red and/or green lentils, well rinsed
2 quarts water or broth
pinch thyme or any herbs of your choice
Salt to taste

Combine first 6 ingredients and bring to boil. Add seasonings. Reduce heat to medium-low and simmer, partially covered, until lentils are soft. Add herbs and salt about 5–10 minutes before cooking is finished. Green lentils need about 45 minutes to 1 hour, while red lentils only need 20–30 minutes. Puree half of the soup in the blender if you prefer a creamy soup.

Meal in a Muffin—*Makes one dozen*

Adapted with permission from "Wheat-free Sugar-Free Gourmet Cooking" by Susan O'Brien, Gig Harbor, WA, 2001

1 medium carrot, grated
 1 large apple, grated
 ¼ cup canola oil
 ¼ cup unsweetened applesauce
 egg replacer to equal 2 eggs (recipe under Baking Tips)
 1/3 cup Mystic Lake Dairy sweetener
 2 tsp. vanilla
 ¼ cup garbanzo bean flour
 ½ cup brown rice flour
 ¼ tsp. cinnamon
 ½ tsp. baking powder
 ¼ tsp. ginger
 1/8 tsp. nutmeg
 ¼ cup shredded unsweetened coconut
 ½ cup chopped dates

Preheat oven to 375 degrees. Mix together all wet ingredients and set aside. In a separate bowl, mix dry ingredients then mix both together. Lightly coat muffin tins with oil spray. Fill 3/4 full and bake 15–20 minutes or until toothpick comes out clean. Allow to cool on a rack.

Mochi Rice Waffles—*Serves 4*

Purchase 1 package of cinnamon-apple Mochi and defrost. Cut into quarters. Slice each quarter across to form 2 thinner squares. Place one square into preheated waffle iron and cook until done. Top with your choice of fruit or sautéed apples (recipe below).

Mock Mac'n Cheese—*Servings depend on amounts of ingredients used*

Cook desired amount of brown rice pasta according to package instructions. Toss cooked pasta with olive oil and sprinkle with several tablespoons of nutritional yeast. The yeast gives the pasta a cheese-like taste.

Mock Pesto—*Makes 1 cup*

Used with permission from "The Allergy Self Help Cookbook," by Marjorie Hurt Jones, R.N. Rodale Press, Emmaus, Pa.

1 large ripe avocado
 1 cup basil leaves
 ¼ tsp. lemon juice
 1 garlic clove, minced or 1/8 tsp. garlic powder
 ¼ cup pine nuts
 ½ tsp. olive or flax oil

Cut the avocado in half and remove the pit. Scoop out the flesh and place it in bowl of a food processor. Add the basil, lemon juice, garlic and pine nuts. Process for about 2 minutes—scrape the bowl as necessary. Transfer it to a small bowl and coat the surface with oil to prevent browning. Chill.

Nutri-Ola (basic recipe)—*Serves 10*

Adapted with permission from "Allergy Recipes," by Sally Rockwell, Nutrition Survival Press, Seattle, Washington

2 cups arrowroot or millet flour or finely ground filberts, pecans, almonds, walnuts, or sesame seeds
 1 cup filberts or walnuts, coarsely ground
 1 cup whole sesame seeds or sunflower seeds (or a combination)
 1 cup (combined) finely chopped dried apples, papaya, apricots, currants
 ½ cup fruit puree or frozen fruit concentrate
 ½ cup sesame or walnut or sunflower oil
 2 tsp. pure vanilla or almond extract

Preheat oven to 275 degrees. Use a blender or food processor to grind nuts, grains, or seeds to desired consistency. Mix the nuts, seeds and/or grains in a large bowl. Mix with fruit and sweetener, oil and vanilla. Pour over the dry mixture and stir lightly. Spread mixture into a lightly oiled 15" x 10" x 1" baking pan. Bake for 1 hour, stirring every 15 minutes. Cool. Break into small pieces for cereal or large chunks for snacks.

Nutty Green Rice—*Serves 4*

1 cup brown basmati rice
 2 cups water
 ¼ to ½ tsp salt
 ½ cup almonds
 1 bunch parsley
 1 clove garlic
 1½ tbsp. lemon juice
 1½ tbsp. olive oil
 ½ cucumber, diced
 pepper to taste

Bring water to a boil, add rice and salt, stir and simmer, covered, for 45 minutes. Remove from heat and let sit for another 10 minutes; then remove cover and allow to cool. While rice is cooking, blend almonds, parsley, garlic, and oil in a food processor. When rice is cool, stir with nut mixture and add pepper to taste. Garnish with cucumber if desired.

Nutty Mayo—Makes 1 ¼ cups. Keeps well for 3 weeks

Adapted and used with permission from “The Allergy Self Help Cookbook,” by Marjorie Hurt Jones, R.N., Rodale Press, Emmaus, Pa.

½ cup cashews or other nuts
¾ cup water
3 tbsp. vinegar
2 tbsp. oil
1 tbsp. arrowroot
1 tbsp. brown rice syrup
1 tbsp. minced parsley
1 tbsp. snipped chives
1 ½ tsp. dry mustard

Grind the nuts to a fine powder in a blender. Add the water, blend 1 minute to make sure the nuts are fully ground. Add the vinegar, oil, arrowroot, sweetener, and seasonings. Blend until very smooth. Pour into a saucepan and cook a few minutes, until thick. Allow to cool, transfer to a glass jar. Store in the refrigerator.

Oven-roasted Veggies—number of servings depends on amount of veggies used

Use any combination of the following vegetables, unpeeled, washed, and cut into bite-sized pieces: eggplant, small red potatoes, red onion, yellow or green summer squash, mushrooms, asparagus. Toss with crushed garlic cloves and olive oil and sprinkle with rosemary, oregano, tarragon, and basil to taste. Spread in roasting pan in single layers and roast approximately 20–25 minutes at 400 degrees until veggies are tender and slightly brown, stirring occasionally. The amount of time needed depends on the size of the veggie pieces. Salt and pepper to taste. Serve while warm, or use cold leftovers in salad.

Pear Honey—Makes 3 pints

Used with permission from “The Allergy Self Help Cookbook,” by Marjorie Hurt Jones, R.N. Rodale Press, Emmaus, Pa.

15 very ripe pears
½ cup water
½ cup brown rice syrup or fruit juice sweetener

Peel, quarter and core the 15 pears. Place 12 of the pears in a stainless steel or enamel Dutch oven or 3 quart saucepan. Coarsely chop the remaining 3 pears. Place them and the water in a blender. Process until pureed. Pour into the pan with the pear quarters.

Bring to a boil, then reduce the heat to a simmer. Stir in the sweetener. Cook until pears are tender, about 30 minutes. Purée the cooked fruit in batches using a blender or food processor. The purée should be about the consistency of honey. If too thin, return it to the pan and boil it down a bit. If too thick, dilute with a little juice. Pour into jars, and store in the refrigerator for up to 1 month.

Pickled Beets—Serves 4–6

Adapted and used with permission from “The Allergy Self Help Cookbook,” by Marjorie Hurt Jones, R.N., Rodale Press, Emmaus, Pa.

4 beets, cooked and skinned
¼ cup water
1 tbsp. brown rice syrup or fruit sweetener
¼ cup rice vinegar
¼ tsp. ground cinnamon
pinch each of cloves and allspice
Combine the water, sweetener, vinegar, cinnamon, cloves and allspice in a medium saucepan. Simmer for 2 minutes. Stir in the beets, and heat through. Serve hot or warm.

Quinoa Salad—Serves 8–10

1 ½ cups quinoa, rinsed several times
3 cups water, or chicken or vegetable broth (or a combination)
1 cup fresh or frozen peas (frozen baby peas should be just defrosted)
chopped veggies, raw or lightly steamed (broccoli, asparagus, green beans, etc.)
½ cup chopped red onion
1 pint cherry tomatoes (optional)
½ cup chopped black olives (optional)
1/3 cup olive oil
2 tbsp. balsamic vinegar or lemon juice
1 or 2 crushed garlic cloves
2–4 tbsp. fresh dill, chopped (or 1 tbsp. dried dill)
2 tbsp. chopped fresh parsley
salt and pepper to taste

Rinse quinoa well (quinoa tastes bitter if not well rinsed). Bring 3 cups water or broth to a boil. Add rinsed quinoa and bring back to boil. Simmer uncovered for about 15 minutes until liquid is well absorbed. Transfer to large bowl with a small amount of olive oil to prevent sticking, and allow to cool. Meantime, mix together remaining oil, vinegar or lemon juice, parsley, and garlic in a small bowl. Add veggies to quinoa and toss well with dressing mixture, dill, salt and pepper. Chill before serving.

Rice Pancakes—Makes approximately 14 (4-inch) pancakes

1 1/3 cups rice flour
½ cup oat or millet flour
2 tsp. baking powder
½ tsp. baking soda
¼ tsp. salt
1 tbsp. apple butter
1 tbsp. safflower or sesame oil
egg replacer to equal 2 eggs (recipe under Baking Tips)
1 ½ cups almond, oat, or rice milk
1 ½ tbsp. white vinegar

Mix the almond or rice milk with the vinegar and allow the mixture to stand for 5 minutes until curdles form. Mix dry ingredients together and set aside. In large mixing bowl, beat apple butter, oil, egg, and milk. Add dry mixture and stir gently. Be careful not to overmix. Serve with sautéed apples (recipe below).

Rice Pasta Primavera—Serves 4

2 cups uncooked rice pasta (noodles, spaghetti, elbows)
1 large whole chicken breast, cut into thin strips (optional)
broccoli florets, chopped carrot, and/or other favorite veggie, lightly steamed
3-4 scallions, chopped
2 cloves garlic, minced
1 tbsp. olive oil (more if needed)
¼ cup fresh basil, finely chopped
¼-½ cup coconut milk
Cook rice pasta according to package directions. While pasta is cooking, heat oil in wok or heavy frying pan, and stir fry chicken strips (or tofu chunks), garlic, scallions, and basil for about 5 minutes; add remaining vegetables and coconut milk and continue to cook until veggies are soft and glisten. Add more coconut milk as needed. Remove from heat and spoon over drained rice pasta and garnish with black olives and extra olive oil, if desired.

Sautéed Apples—Serves 2

2 apples, washed
½ tbsp. safflower oil or canola oil
2 tsp. cinnamon
2-3 tbsp. apple juice

Thinly slice apples and sauté in oil until softened. Add cinnamon and apple juice and simmer, stirring, uncovered for a few more minutes.

Spiced Lentil Casserole—Serves 4

1 ½ cups lentils, rinsed well
2 tbsp. sesame oil
3 cloves garlic, crushed
1 stalk celery, chopped
1 large onion, chopped
½ tsp. salt
1 cup shredded, unsweetened coconut
½ tsp. cinnamon
½ tsp. powdered ginger
½ tsp. turmeric
2 large green apples, washed and diced

Simmer lentils, covered, in 2 ½ cups water for 30-40 minutes, until tender. While they are cooking, in a wok or heavy skillet, sauté remaining ingredients, except apples, in oil until tender. Add water as necessary. Add apples and cook 10 more minutes covered. Combine with cooked lentils in a casserole dish.

Split Pea Soup—Serves 6

3 cups dry split peas, well rinsed
2 quarts water
1 tsp. salt
1 bay leaf
½-1 tsp. dry mustard
2 onions, chopped fine
4 cloves garlic, minced
3 stalks celery, chopped
2 medium carrots, sliced
salt and pepper to taste
3 tbsp. apple cider vinegar or rice vinegar

Combine peas, water, salt, bay leaf, and mustard in 6-quart pot. Bring to boil, reduce heat and simmer, partially covered for about 20 minutes. Add vegetables and simmer for another 40 minutes, stirring occasionally. Add more water as needed. Add salt, pepper, and vinegar to taste.

Sweet Potato Delight—Serves 1-2

Adapted and used with permission from "The Allergy Self Help Cookbook," by Marjorie Hurt Jones, R.N., Rodale Press, Emmaus, Pa.

2-4 tbsp. chopped nuts
1 ripe banana
1 medium sweet potato, cooked
1 tsp. oil
1 tbsp. fruit sweetener, molasses, or brown rice syrup (optional)

In a large frying pan, dry roast the nuts over medium heat for a few minutes. Shake the pan often. Cut the banana in half lengthwise. Cut the cooked sweet potato into ½" pieces. Add the oil to the pan. Push the nuts to the outer edges. Place the banana pieces, flat sides down, in the pan. Add the sweet potatoes. Cover and cook for 2 minutes. Uncover, and cook for 5 minutes, until everything is heated through and browned on one side. Add the sweetener before serving.

Vinaigrette Dressing—6 servings (approximately)

Note: Ingredient amounts in this recipe are approximate; use more or less of certain ingredients to adapt recipe to your personal taste.

¼ cup each flax and extra-virgin olive oils
3 tbsp. balsamic vinegar (preferred because it has the richest flavor)
2-3 tbsp. water
1 tsp. dry mustard
1-3 cloves fresh garlic (whole pieces for flavor or crushed for stronger taste)
Salt and pepper to taste
Oregano, basil, parsley, tarragon or any herbs of your choice, fresh or dried

Place vinegar, water, and mustard in a tightly capped jar, and shake well to thoroughly dissolve mustard. Add oil and remaining

ingredients and shake well again. Refrigerate and shake well before using. Dressing will harden when cold; allow 5-10 minutes to re-liquify.

Baking Tips

Finely-ground nut meal is included in muffin recipes, in addition to chopped nuts, because it helps retain moisture and allows for a small amount of leavening.

To grind soft nuts such as walnuts or pecans, use 1–2 tbsp. of the starch called for in the recipe and add to the grinding mixture to prevent clumping.

The grinding may be done with a nut chopper, a small (very clean) coffee grinder, or by pulsing on a food processor. Particles should be fine enough to pass through a strainer. Grind only what you will need. If you are allergic to nuts, replace the amount of nut flour with an equal amount of another flour or starch called for in the recipe.

Egg Replacer (equals one egg)

1/3 cup water
1 tbsp. whole or ground flaxseed

Combine the water and flaxseed and allow to jell for about 5 minutes. This mixture will bind patties, meat loaves, cookies, and cakes as well as eggs do, but it will not leaven like eggs for souffles or sponge cakes. Increase amounts accordingly for additional egg replacement.

Corn Free Baking Powder

2 tsp. cream of tartar
2 tsp. arrowroot
1 tsp. baking soda

Sift together to mix well. Store in an airtight container. Make small batches.

Table 1. Typical Foods to Include and Exclude on an Elimination Diet Program

	Include	Exclude
Fruits	Whole fruits, unsweetened, frozen or water-packed, canned fruits and diluted juices	Oranges and orange juice
Dairy and dairy substitutes	Rice, oat, and nut milks such as almond milk and coconut milk	Dairy and eggs: milk, cheese, eggs, cottage cheese, cream, yogurt, butter, ice cream, frozen yogurt, non-dairy creamers
Grains and starch	Brown rice, oats, millet, quinoa, amaranth, teff, tapioca buckwheat, potato flour	Grains: corn and non-gluten grains: wheat, barley, spelt, kamut, rye, triticale
Animal protein	Fresh or water-packed fish, wild game, lamb, duck, organic chicken and turkey	Pork, beef/veal, sausage, cold cuts, canned meats, frankfurters, shellfish
Vegetable protein	Split peas, lentils, and all dried beans other than soybeans	Soybean products (soy sauce, soybean oil in processed foods; tempeh, tofu, soy milk, soy yogurt, textured vegetable protein)
Nuts and seeds	Sesame, pumpkin, and sunflower seeds, walnuts, hazelnuts, pecans, almonds, cashews, nut butters such as almond or tahini	Peanuts and peanut butter
Vegetables	All raw, steamed, sautéed, juiced or roasted vegetables	Corn, creamed vegetables
Oils	Cold-pressed olive, flax, walnut, safflower, grapeseed, sesame, almond, sunflower, canola, pumpkin, and coconut oils	Butter, margarine, shortening, processed oils, salad dressings, mayonnaise, and spreads
Drinks	Filtered or distilled water, non-caffeinated herbal teas, seltzer or mineral water	Alcohol, coffee and other caffeinated beverages, soda pop or soft drinks
Sweeteners	Brown rice syrup, agave nectar, stevia, fruit sweeteners, blackstrap molasses	Refined sugar, white/brown sugars, honey, maple syrup, high fructose corn syrup, evaporated cane juice, sucanat
Condiments	Vinegar, all spices, including salt, pepper, basil, carob, cinnamon, cumin, dill, garlic, ginger, mustard, oregano, parsley, rosemary, tarragon, thyme, turmeric	Chocolate, ketchup, relish, chutney, soy sauce, barbecue sauce, teriyaki, and other condiments

Read Ingredient Labels Carefully! Things to watch for:

Corn starch in baking powder and any processed foods.

Corn syrup in beverages and processed foods.

Vinegar in ketchup, mayonnaise and mustard is usually from wheat or corn.

Breads advertised as gluten-free may contain spelt, kamut, rye.

Many amaranth and millet flake cereals have corn.

Many canned tunas contain textured vegetable protein, which is from soy.

Look for low-salt versions which tend to be pure tuna, with no fillers.

Multi-grain rice cakes may not be just rice. Purchase plain rice cakes.

Table 2. Sample Shopping List for Use with an Elimination Diet

Fruits	Onions Pak-Choi Parsley Potato Red leaf chicory Sea vegetables—seaweed, kelp Snow peas Spinach Squash Sweet potato & yams Swiss chard Tomato Watercress Zucchini <i>All the above vegetables can be consumed raw, juiced, steamed, sautéed, or baked.</i>

Table 3. Sample Food Reintroduction Tracking Form

Date or Day	Food		Digestion/ Bowel Function	Joint/ Muscle Aches	Headache Pressure	Nasal or Chest Congestion	Kidney- Bladder Skin Function	Energy Level
	Time	Food						

Note: Please reintroduce only one new food at a time. Ingest it 2–3 times in the same day, and then assess your response over the next 48 hours. Wait two full days to see whether you have a reaction. You may insert different headings on this chart to correspond with whatever signs or symptoms you experience. Important indicators that must be charted include: digestion, bowel function, and energy level. If you require more space, use the back of this sheet and clearly mark the day, the food, and your symptoms. If you are unsure whether you had a reaction, retest the same food in the same manner (after the two-day waiting period).

Cytochrome P450 Enzymes: Drug and Natural Product Substrates, Inhibitors, and Inducers

Cytochrome P450 1A2				
Drug Substrate	Natural Substrate	Inhibitors	Inducers	
Acetaminophen	Riluzole	Cabbage	Amiodarone	Carbamazepine
Amitriptyline—Elavil	Ropinirole	Ginkgo leaf	Cimetidine	Charbroiled food
Caffeine	Ropivacaine	Grapefruit skin	Ciprofloxacin	Cruciferous vegetables
Chlordiazepoxide	Tacrine: Cognex	Indole-3-carbinol	Citalopram	Lansoprazole
Clomipramine—Anafranil	Theophylline—Theo-Dur	Ipri flavone	Clarithromycin	Omeprazole
Clopidogrel—Plavix	Verapamil—Calan	Nutmeg	Diltiazem	Phenobarbital
Clozapine—Clozaril	R-warfarin	Mace	Enoxacin	Phenytoin
Cyclobenzaprine—Flexeril	Zileuton—Zyflo	Ipri flavone	Erythromycin	Primidone
Desipramine—Norpramin	Zolmitriptan—Zomig	St. John's Wort	Acetaminophen	Rosemary
Diazepam—Valium			Fluvoxamine	Rifampin
Estradiol—Estrace			Hops	Ritonavir
Flutamide			Isoniazid	Smoking
Fluvoxamine—Luvox			Ketoconazole	St. John's Wort
Haloperidol—Haldol			Methoxsalen	
Imipramine—Tofranil			Mexiletine	
Levobupivacaine			Nalidixic acid	
Mexiletine—Mexitil			Norethindrone	
Mirtazapine—Remeron			Norfloxacin	
Naproxen			Omeprazole	
Nortriptyline			Oral contraceptives	
Olanzapine—Zyprexa			Paroxetine	
Ondansetron—Zofran			Tacrine	
Pentazocine—Talwin			Ticlopidine	
Propafenone			Troleandomycin	
Propranolol—Inderal			Zileuton	

Cytochrome P450 2C9				
Drug Substrate	Natural Substrate	Inhibitors	Inducers	
Amitriptyline—Elavil	Omeprazole	Ipriflavone	Amiodarone	Aprepitant
Carvedilol	Ondansetron—Zofran	St. John's Wort	Chloramphenicol	Carbamazepine
Celecoxib	Phenytoin		Cimetidine	Phenobarbital
Clomipramine—Anafranil	Piroxicam		Clopidogrel	Primidone
Clopidogrel—Plavix	Rosiglitazone		Cotrimoxazole	Rifampin
Clozapine—Clozaril	Sildenafil		Delavirdine	Rifapentine
Desogestrel	Sulfamethoxazole		Disulfiram	
Diazepam—Valium	Tacrine—Cognex		Efavirenz	
Diclofenac	Tolbutamide		Fenofibrate	
Dronabinol	Torsemide		Fluconazole	
Estradiol (Estrace)	Valdecoxib		Fluorouracil	
Fluoxetine—Prozac	Valsartan		Fluoxetine	
Flurbiprofen	Verapamil—Calan		Fluvastatin	
Fluvastatin—Lescol	Voriconazole		Fluvoxamine	
Formoterol	S—Warfarin—Coumadin		Gemfibrozil	
Glimepiride	Zafirlukast		Imatinib	
Glipizide	Zileuton-Zyflo		Isoniazid	
Glyburide			Itraconazole	
Grepafloxacin—Raxar			Ketoconazole	
Ibuprofen			Leflunomide	
Imipramine—Tofranil			Lovastatin	
Indomethacin			Metronidazole	
Irbesartan			Milk Thistle	
Losartan—Cozaar			Modafinil	
Mefenamic acid			Omeprazole	
Meloxicam			Paroxetine	
Mirtazapine—Remeron			Sertraline	
Montelukast			Sulfonamides	
Naproxen			Ticlopidine	
Nateglinide			Voriconazole	
			Zafirlukast	

Cytochrome P450 2C19			
Drug Substrate	Natural Substrate	Inhibitors	Inducers
Amitriptyline—Elavil	Phenytoin	Citalopram	Carbamazepine
Carisoprodol	Progesterone	Delavirdine	Norethindrone
Cilostazol	Proguanil	Efavirenz	Phenobarbital
Citalopram	Propranolol—Inderal	Felbamate	Phenytoin
Clomipramine—Anafranil	Rabeprazole	Fluconazole	Prednisone
Cyclophosphamide	Teniposide	Fluoxetine	Rifampin
Desipramine—Norpramin	Thioridazine	Fluvastatin	
Diazepam—Valium	Tolbutamide	Fluvoxamine	
Esomeprazole	Voriconazole	Indomethacin	
Formoterol	R-warfarin	Isoniazid	
Hexobarbital		Ketoconazole	
Imipramine—Tofranil		Letrozole	
Indomethacin		Modafinil	
Lansoprazole—Prevacid		Omeprazole	
Mephobarbital		Oxcarbazepine	
Moclobemide		Paroxetine	
Nelfinavir		Sertraline	
Nilutamide		Telmisartan	
Omeprazole		Ticlopidine	
Pantoprazole		Topiramate	
Pentamidine		Voriconazole	

Cytochrome P450 2D6				
Drug Substrate	Natural Substrate	Inhibitors	Inducers	
Amitriptyline—Elavil	Meperidine	Ginkgo leaf	Amiodarone	Carbamazepine
Amphetamine	Methadone	Ginseng, Panax	Bupropion	Ethanol
Atomoxetine	Methamphetamine	St. John's Wort	Celecoxib	Phenobarbital
Bisoprolol	Methoxyamphetamine		Chloroquine	Phenytoin
Carvedilol	Metoprolol		Chlorpheniramine	Primidone
Cevimeline	Mexiletine—Mexitil		Cimetidine	Rifampin
Chlorpromazine	Mirtazapine—Remeron		Citalopram	Ritonavir
Chlorpropamide	Morphine		Clomipramine	St. John's Wort
Clomipramine—Anafranil	Nortriptyline		Cocaine	
Clozapine—Clozaril	Olanzapine		Desipramine	
Codeine	Ondansetron—Zofran		Diphenhydramine	
Cyclobenzaprine—Flexeril	Oxycodone		Fluoxetine	
Desipramine—Norpramin	Paroxetine		Fluphenazine	
Dexfenfluramine	Perphenazine		Halofantrine	
Dextromethorphan	Pindolol		Haloperidol	
Dolasetron	Propafenone		Hydroxychloroquine	
Donepezil—Aricept	Propoxyphene		Imatinib	
Doxepin	Propranolol—Inderal		Levomepromazine	
Encainide	Quetiapine		Methadone	
Fenfluramine	Risperidone		Moclobemide	
Fentanyl—Duragesic	Thioridazine		Norfluoxetine	
Flecainide	Tramadol		Paroxetine	
Fluoxetine—Prozac	Trazodone		Perphenazine	
Fluphenazine	Venlafaxine		Propafenone	
Fluvoxamine—Luvox			Propoxyphene	
Formoterol			Quinacrine	
Galantamine			Quinidine	
Haloperidol—Haldol			Ranitidine	
Hydrocodone			Ritonavir	
Imipramine—Tofranil			Sertraline	
Lidocaine			Terbinafine	
Maprotiline			Thioridazine	

Cytochrome P450 3A4				
Drug	Substrate	Natural Substrate	Inhibitors	Inducers
Alfentanil	Dronabinol	American elder	Acitretin	Aminoglutethimide
Almotriptan	Dutasteride	Bishop's weed	Amiodarone	Acetaminophen
Alprazolam	Efavirenz	Bitter orange	Amprenavir	Carbamazepine
Amitriptyline—Elavil	Ergotamine	Cat's claw	Aprepitant	Dexamethasone
Amiodarone	Erythromycin	Chamomile	Cimetidine	Efavirenz
Amlodipine	Esomeprazole	DHEA	Ciprofloxacin	Ethosuximide
Amprenavir	Estrogens, contraceptives	Echinacea	Clarithromycin	Garlic
Aprepitant	Ethinyl estradiol	Elder root	Cyclosporine	Glucocorticoids
Atorvastatin	Ethosuximide	Garlic	Danazol	Glutethimide
Bepridil	Etonogestrel	Ginkgo leaf extract	Delavirdine	Griseofulvin
Bexarotene	Etoposide	Goldenseal	Diltiazem	Modafinil
Bromocriptine	Exemestane	Licorice	Diethyl-	Nafcillin
Budesonide	Felodipine	Milk thistle	dithiocarbamate	Nevirapine
Buprenorphine	Fentanyl—Duragesic	Red clover	Efavirenz	Oxcarbazepine
Buspirone	Fexofenadine	Red yeast	Eleuthera	Phenobarbital
Busulfan	Finasteride	Saw palmetto	Erythromycin	Phenytoin
Cannabinoids	Flutamide	St. John's wort	Acetaminophen	Primidone
Caffeine	Fluticasone	Valerian	Fluconazole	Rifabutin
Carbamazepine	Fulvestrant	Wild cherry bark	Fluoxetine	Rifampin
Cevimeline	Galantamine		Fluvoxamine	Rifapentine
Chlorpheniramine	Haloperidol—Haldol		Gestodene	St. John's Wort
Cilostazol	Hydrocodone		Grapefruit	
Cisapride	Hydrocortisone		Indinavir	
Citalopram	Ifosfamide		Imatinib	
Clarithromycin	Imatinib		Isoniazid	
Clindamycin	Imipramine—Tofranil		Itraconazole	
Clomipramine—Anafranil	Indinavir		Ketoconazole	
Clonazepam	Isradipine		Metronidazole	
Clopidogrel—Plavix	Itraconazole		Methylprednisone	
Cocaine	Ketoconazole		Miconazole	
Cyclobenzaprine—Flexeril	Lansoprazole—Prevacid		Mifepristone	
Cyclophosphamide	Letrozole		Milk Thistle	
Cyclosporine	Levobupivacaine		Nefazodone	
Dapsone	Lidocaine		Nelfinavir	
Delavirdine	Lopinavir		Nicardipine	
Desogestrel	Loratadine		Nifedipine	
Dexamethasone	Losartan—Cozaar		Norethindrone	
Dextromethorphan	Lovastatin		Norfloracin	
Diazepam—Valium	Methadone		Norfluoxetine	
Dihydroergotamine	Methylprednisolone		Oxiconazole	
Diltiazem	Miconazole		Prednisone	
Disopyramide	Midazolam		Quinine	
Docetaxel	Mifepristone		Ritonavir	
Dofetilide	Mirtazapine—Remeron		Roxithromycin	
Dolasetron	Modafinil		Saquinavir	
Donepezil—Aricept	Mometasone		Sertraline	
Doxorubicin	Montelukast		Synercid	

Cytochrome P450 3A4 (Continued)			
Drug Substrate	Natural Substrate	Inhibitors	Inducers
Nateglinide	Salmeterol	Troleandomycin	
Nefazodone	Saquinavir	Verapamil	
Nelfinavir	Sertraline	Voriconazole	
Nevirapine	Sibutramine	Zafirlukast	
Nicardipine	Sildenafil	Zileuton	
Nifedipine	Simvastatin		
Nimodipine	Sirolimus		
Nisoldipine	Tacrolimus		
Nitrendipine	Tamoxifen		
Nortriptyline	Temazepam		
Norethindrone	Testosterone		
Omeprazole	Tiagabine		
Ondansetron—Zofran	Tolterodine		
Oral contraceptives	Toremifene		
Oxybutynin	Tramadol		
Paclitaxel	Trazodone		
Pantoprazole	Triazolam		
Pimozide	Trimetrexate		
Pioglitazone	Valdecoxib		
Prednisolone	Verapamil- Calan		
Prednisone	Vinblastine		
Progesterone/Progestins	Vincristine		
Quetiapine	Vinorelbine		
Quinidine	Voriconazole		
Quinine	R-warfarin		
Rabeprazole	Zaleplon		
Repaglinide	Zileuton-Zyflo		
Rifabutin	Ziprasidone		
Rifampin	Zolpidem		
Ritonavir	Zonisamide		

Detailed Review of Systems

General	Fever, weight loss, weight gain. Are you at the weight you want? How much time do you exercise per day ____, per week ____? Hours of sleep per night? Any problems with sleep?
Head	Headaches, migraine, trauma, vertigo, syncope, convulsive seizures.
Eyes	Visual loss or color blindness, diplopia, hemianopsia, trauma, inflammation, glasses (date of refraction). Cataracts, decreased vision or blindness at night.
Ears	Deafness, tinnitus, vertigo, discharge from the ears, pain, mastoiditis, operations. Sounds you have trouble hearing.
Nose	Coryza, rhinitis, sinusitis, discharge, obstruction, epistaxis, polyps, deviation of septum, operations.
Mouth	Soreness of the mouth or tongue, gingivitis, change in taste, tooth pain, aphthous ulcers.
Throat	Sore throats, tonsillitis, voice changes, hoarseness, polyps, difficulty swallowing.
Neck	Swelling, suppurative lesions, enlargement of the lymph nodes, goiter, stiffness, limitation of motion.
Breasts	Development, lactation, trauma, lumps, pains, discharge from nipples, gynecomastia, changes in nipples, soreness, previous biopsies.
Respiratory	Pain, shortness of breath, wheezing dyspnea, nocturnal dyspnea, orthopnea, cough, sputum, hemoptysis, night sweats, pleurisy, bronchitis, tuberculosis (history of contacts), pneumonia, asthma, other respiratory infections—coccidioidomycosis, histoplasmosis exposures.
Cardiovascular	Palpitation, tachycardia, irregularities of rhythm, pain in the chest, exertional dyspnea, paroxysmal nocturnal dyspnea, orthopnea, cough, cyanosis, ascites, edema. Intermittent claudication, cold extremities, phlebitis, postural or permanent skin color changes. Hypertension rheumatic fever, chorea, syphilis, diphtheria. When you exercise how fast do you get your heart rate? ____% Maximal predicted heart rate ($220 - \text{age} = \text{____}$). Wheezing with exercise. Problems walking up a hill. Do you get short of breath or have chest pain when vacuuming, raking, or shoveling snow or dirt?
Gastrointestinal	Appetite, anorexia, dysphagia, nausea, eructations, flatulence, abdominal pain or colic, vomiting, hematemesis, jaundice (pain, fever, intensity, duration, color of urine and stools), stools (color, frequency, consistency, odor, gas, cathartics), hemorrhoids—internal/external. Change in bowel habits.
Genitourinary	Color of urine, polyuria, oliguria, nocturia, dysuria, hematuria, pyuria, urinary retention, urinary frequency, incontinence, pain or colic, passage of stones or gravel. Menstrual history: Age of onset, frequency of periods, regularity, duration, amount of flow, leukorrhea, dysmenorrhea, date of last normal and preceding periods, date and character of menopause, postmenopausal bleeding. Pregnancies: Number, abortions, miscarriages, stillbirths, chronologic sequence, complications of pregnancy. Venereal history: Chancre, bubo, penile or vaginal discharge. Treatment of venereal diseases. Sexual history: Age of onset of sexual relations, single partner or number of partners, libido, ability to orgasm, erectile dysfunction, sexual preference, satisfaction. Fertility issues?

Nervous system	Disturbances of smell (1), visual disturbances (2,3,4,6); orofacial paresthesias and difficulty in chewing (5); facial weakness and taste disturbances (7); disturbances in hearing and equilibrium (8); difficulties in speech, swallowing and taste (9,10,12); limitation in motion of neck (11). Motor system: Paralysis, atrophy, involuntary movements, convulsions, gait, incoordination Sensory system: Pain, lightning pain, girdle pain, paresthesia, hypesthesia, anesthesia. Autonomic system: Control of urination and defecation, sweating, erythema, cyanosis, pallor, reaction to heat and cold.
Mental status	Describe reactions to and influence of parents, siblings, spouse, children, friends and associates, sexual adjustments, successes and failures, illnesses. Lability of mood, hallucinations, grandiose ideas, sleep disturbances. How is your memory—short term, long term? Any memory frustrations?
Skin	Color, pigmentation, temperature, moisture, eruptions, pruritus, scaling, bruising, bleeding. Hair: Color, texture, abnormal loss or growth, distribution. Nails: Color changes, brittleness, ridging, pitting, curvature or white spots.
Lymph nodes	Enlargement, pain, suppuration, draining sinuses, location.
Bones, joints, muscles	Fractures, dislocations, sprains, arthritis, myositis, pain, swelling, stiffness, migratory distribution, degree of disability, muscular weakness, wasting, or atrophy. Night cramps.
Hematopoietic	Anemia (type, therapy, and response), lymphadenopathy, bleeding (spontaneous, traumatic, familial).
Endocrine	History of growth, body configuration and weight. Size of hands, feet, and head, especially changes during adulthood. Hair distribution, skin pigmentation, weakness, goiter, exophthalmos, dryness of skin and hair, intolerance to heat or cold, tremor. Polyphagia, polydipsia, polyuria, glycosuria. Secondary sex characteristics, impotence, sterility, treatment. Sun exposure/week.
Immunologic and allergy	Dermatitis, urticaria, angioneurotic edema, eczema, hay fever, vasomotor rhinitis, asthma, migraine, vernal conjunctivitis. Seasonal incidence of previous conditions. Known sensitivity to pollens, foods, danders, or drugs. Previous skin tests and their results. Results of tuberculin tests and others. Desensitization, vaccinations and immunizations. Lyme disease. Mold sensitivities. HIV exposures or concerns. Hepatitis exposures or concerns.

Adapted from Degowin EL and Degowin RL. Bedside Diagnostic Examination. 3rd Edition. Macmillan Publishing Co.,1975, p. 24-26.

Adult Toxin Exposure Questionnaire

Considering the LAST 12 MONTHS, do you have regular exposure to anything in the lists below?

Please check:

(Y) Yes

(N) No

(?) Unknown

(P) for exposure more than 12 months ago

Community

Do you have regular exposure to:	Y	N	?	P	Notes
Automobile exhaust					
Farm/Industrial/Power plant or lines					
Radio tower					
Landfill/Dump					
Hydro tower					

Home and/or Work Environment

Do you live in a: (Circle one)

House

Apartment Building

Mobile Home

Do you work in: (Circle one)

House

Office Building

Factory

Outdoors

Bathing/Showering water source: (Circle one)

Well

Public Works

Bottled

Do you have regular exposure to:	Y	N	?	P	Notes
Forced air heat					
Renovations (new carpets, add-ons, etc.)					
Basement cracks or dirt floor					
Damp basement or crawl space					
Wet windows or outside closet walls					
Water leaks (ceilings, walls, floors)					
Visible mold					
Old or cracking ceiling tiles					
Old or cracking vinyl linoleum flooring					

Do you have regular exposure to:	Y	N	?	P	Notes
Crumbling pipe insulation					
Crumbling wall or ceiling insulation					
Old or cracking paint					
Carpets or rugs					
Stagnant or stuffy air					
Gas or propane stove					
Coal or wood stove					
Other gas appliance (water heater, furnace)					

Hobby and Work Activities

Do you have regular exposure to:	Y	N	?	P	Notes
Contact with smokers					
Pesticides or herbicides					
Harsh chemicals (varnish, glue, gas, acid, etc.)					
Welding or soldering					
Metals (lead, mercury, etc.)					
Paints					
Photo developing/Dark room					
Airplane travel					
Cleaning chemicals					

Diet

Drinking/Cooking water source:

Well

Public Works

Bottled

Filtered

Caffeine?

What kind:

How much:

Do you regularly consume:	Y	N	?	P	Notes
Fish (fresh, frozen, canned, etc.)					
Artificial sweeteners (circle all that apply): NutraSweet, Equal, Aspartame, Splenda					
Alcohol - If yes, how much? - How often?					
Animal products - How often? - What percentage of your animal product consumption is organic?					
Do you wash your produce? What percentage of your produce is organic?					
Deep fat fried foods					
Sodas, juices, drinks containing high fructose corn syrup. If yes, how many per day?					
Do you have:	Y	N	?	P	
Allergies					
Sensitivity to smells (gas, perfume, paint, etc.)					
Artificial materials in the body (implants, pins, joints, etc.)					
Immunizations					
Have you ever:	Y	N	?	P	
Used tobacco					
Experimented with recreational drugs					
Led a high-stress lifestyle					
Experienced a stressful or traumatic event					
Been under anesthesia					
Had an illness during foreign travel					
Had an illness while camping or hiking					
Had food poisoning					

Dental Care

	Y	N	?	P	Notes
Do you currently have amalgam fillings or caps? How many amalgam fillings do you have now?					
Have you removed or lost dental fillings or caps?					
Did you have fillings as a child? How many fillings did you have?					
Have your wisdom teeth been removed? - At what age? - Any complications such as dry socket or abscesses?					
Have you had any root canals? How many and when were they placed?					
Did your mother have dental fillings prior to giving birth to you? During her pregnancy with you?					
Other:					

Please list all **PRESCRIPTION** or **OVER THE COUNTER** medications you currently take on a regular basis, including birth control pills and allergy injections:

Name of medication	Dose (mg, ML, IU)	How often do you take it?	How long have you taken it?	If you have side effects, please specify

Please list all **VITAMINS/MINERALS**, **HERBS**, or **OTHER SUPPLEMENTS** you currently take on a regular basis:

Name of supplement	Dose (mg, ML, IU)	How often do you take it?	How long have you taken it?	If you have side effects, please specify

Adverse Reactions: Please list ANY medication, anesthetics, immunizations, herbs or supplements you have had to stop taking because of side effects or allergic reactions:

Name of medication/ immunization	Type of side effects or allergic reaction that caused you to stop it	Age	Year

Child Toxin Exposure Questionnaire

Considering the LAST 12 MONTHS, does your child have regular exposure to anything in the lists below?
Please check:

- (Y) Yes
- (N) No
- (?) Unknown
- (P) for exposure more than 12 months ago

Community

Does your child have regular exposure to:	Y	N	?	P	Notes
Automobile exhaust					
Farm/Industrial/Power plant or lines					
Radio tower					
Landfill/Dump					
Hydro tower					

Home and/or Work Environment

- Where does your child live? (Circle one)
- House Apartment Building Mobile Home
- If he/she works, where? (Circle one)
- House Office Building Factory
- Bathing/Showering water source: (Circle one)
- Well Public Works Bottled

Does your child have regular exposure at home or work to:	Y	N	?	P	Notes
Forced air heat					
Renovations (new carpets, add-ons, etc.)					
Basement cracks or dirt floor					
Damp basement or crawl space

Name of medication/immunization	Type of side effects or allergic reaction that caused your child to stop it	Age	Year

Health Benefits of Exercise

System	Increases	Decreases
Cardiovascular	HDL cholesterol Cardiac output Fibrinolytic activity in Response to venous occlusion Increases arteriolar diameter	Serum triglycerides Heart rate CRP Incidence of cardiac arrest Coronary mortality Coronary artery occlusion Peripheral arteriolar resistance Blood pressure
Endocrine		
Diabetes	Improves glucose tolerance Concentration of insulin receptors	Insulin requirements
Hyperlipidemias	HDL cholesterol	Serum triglycerides
Metabolic rate	Increases Caloric expenditure Proportion of lean body mass	Proportion of fat Body weight
Mood	Endorphins	Depression scores
Respiratory disease	Exercise endurance Cognition Work tolerance VO2 max	Breathlessness
Skeletal	Bone retention Muscle mass Sleep Balance Muscle strength Coordination	Number of falls
Overall health	Mobility, strength, endurance Overall longevity	Chronic disease risk Desire for alcohol, smoking

Internet-based Resources for the Healthcare Practitioner

<http://medicine.iupui.edu/flockhart/>

This site provides a table that is designed as a hypothesis testing, teaching and reference tool for physicians and researchers interested in drug interactions that are the result of competition for, or effects on, the human cytochrome P450 system.

PDR net for physicians

<http://www.pdr.net/pdrnet/librarian/>

Database containing 15 full text journals, PDR drug book, PDR drug interactions book. Medical news is also posted, and Medline can be accessed. Free to some health professionals.

MD consult

<http://www.mdconsult.com>

A library of 48 full text journals, 36 books, medical news, and Medline access. Subscription. Free 10-day trial for physicians.

Medscape

<http://www.medscape.com/px/splash>

Access to 62 full text journals, many non-journal periodicals and professional publications, Medline, online medical textbooks, and journal scanning to extract highlights from recent literature within chosen fields. Conference listings; direct CME offerings; news items.

WebMD

<http://www.webmd.com>

Consumer-focused content. Medscape is their physician content site. This site provides access to a wide array of physician-focused and medical office Internet-based services.

Databases, Research, and Scientific Resources

Organizing Medical Networked Information (OMNI)

<http://omni.ac.uk/>

OMNI offers free access to a searchable catalogue of Internet sites covering health and medicine.

Merck Manual

<http://www.merck.com/mrkshared/mmanual/home.jsp>

This website provides access to the 17th edition of the Merck Manual.

Harvard Department of Molecular and Cellular Biology

<http://mcb.harvard.edu/Biolinks.html>

Rosenthal Directory of Databases

www.rosenthal.hs.columbia.edu/Databases.html

This website provides a compilation of established sources in the U.S., Europe and Asia, designed to facilitate research by both professionals and the public in clinical, biomedical, review, meta-analytical or survey research. Many of the databases listed do charge a fee.

MedWeb Plus

<http://medwebplus.com/about.html>

From the site: Our goal at MedWebPlus is to give users tools to quickly locate and assimilate good and reliable information covering the entire spectrum of healthcare.

Cancer Detection and Prevention Online

<http://www.cancerprev.org/>

This is an International Society for Preventive Oncology (ISPO) website that offers access to current and past issues of Cancer Detection and Prevention journals. \$225 annual subscription fee. Some free browsing.

Pesticides, Metals, & Chemical

<http://vm.cfsan.fda.gov/~lrd/pestadd.html>

This is U.S. FDA/Center for Food Safety and Applied Nutrition (CFSAN) website provides information regarding pesticides, metals, and chemical contaminants in food(s).

BioMedNet

<http://www.biomednet.com/>

This website provides information for biological and medical researchers. It offers access to a full-text library (over 170 biological and medical journals), and BioMedLink (evaluated and annotated database of internet resources for biological and medical researchers). Access to Medline reviews of 3500 websites. Free registration.

Medical Biochemistry Subject List

<http://web.indstate.edu/thcme/mwking/subjects.html>

This website offers details on specific biochemistry and medical subjects.

Elsevier Science

<http://www.elsevier.nl/>

This website provides access to purchasing of research publications and journals in the physical, life and social sciences.

The Lancet

<http://www.thelancet.com/>

British Medical Journal

<http://bmj.com/>

All articles of BMJ are available for free online.

NLM Clinical Trials Database

<http://clinicaltrials.gov>

Location, design, purpose, criteria and other information on NIH clinical trials.

PubMed

<http://www.ncbi.nlm.nih.gov/PubMed/>

National Library of Medicine; free access to Medline.

USDA Nutrient Database

http://www.nal.usda.gov/fnic/cgi-bin/nut_search.pl

This interface allows simple searches on the USDA Nutrient Database

General Resources**National Center for Complementary and Alternative Medicine (NCCAM)**

<http://nccam.nih.gov>

This is a NIH website offering fairly comprehensive information regarding alternative therapies. Includes Consensus Reports, research, clinical trials, database links.

NIH Office of Dietary Supplements

<http://odp.od.nih.gov/>

The International Bibliographic Information on Dietary Supplements (IBIDS) is a NIH website produced by the Office of Dietary Supplements (ODS). It offers a database of published, international, scientific literature on dietary supplements, including vitamins, minerals, and botanicals. Search can be limited to peer-reviewed publications.

Herb Research Foundation (HRF)

<http://www.herbs.org/>

A nonprofit research and educational organization focusing on herbs and medicinal plants.

American Botanical Council's Herbal Information

<http://www.herbalgram.org/>

This website provides information about herbs that have been compiled from a number of reputable scientific sources including the German Commission E Monographs, Botanical Safety Handbook, and numerous clinical trials that have been referenced in HerbalGram, their quarterly publication.

Healthfinder

<http://www.healthfinder.gov>

This website provides consumer health and human services information developed by the U.S. Department of Health and Human Services. It provides access to selected online publications, clearinghouses, databases, websites, and support and self-help groups.

NIH Consumer Health Information

<http://health.nih.gov/>

This website provides access to consumer publication titles specific to certain conditions/diseases.

HealthGate

<http://www.healthgate.com/>

This website provides patient and consumer information regarding drugs and vitamins, symptoms and medical tests, and general health. It also provides access to Medline. Provider of web-enabled technology and services for healthcare organizations, including hospitals.

Medherb

<http://medherb.com/>

This website of Medical Herbalism, a quarterly journal of clinical herbalism. It provides links to medical information and to any resource relevant to medicinal herbs or herbalism practiced in clinical settings, plus sample articles on hundreds of herbs.

The World Lecture Hall

<http://www.utexas.edu/world/lecture/>

This website provides links to pages created by faculty worldwide who are using the web to deliver university-level academic courses in any language.

Food Allergy and Anaphylaxis Network (FAAN)

<http://www.foodallergy.org/>

This website provides access to FAAN, a nonprofit organization established to increase public awareness about food allergy and anaphylaxis. It offers, among other things, a bimonthly newsletter, product alerts, and updates on food allergy.

Dr. Duke's Phytochemical and Ethnobotanical Databases

<http://www.ars-grin.gov/duke/>

Database of phytochemical ingredients for herbs and spices.

<http://www.essentialfats.com>

This website presents information about the role of essential fatty acids in health and disease. It includes discussions on fatty acid analysis, research results, new diagnostic and treatment approaches of fatty acids in such areas as lipid abnormalities and inflammatory bowel disease.

Medical Symptoms Questionnaire

Name: _____ Date: _____

Rate each of the following symptoms based upon your typical health profile for:

☐ Past 30 days ☐ Past 48 hours**Point Scale**

0 - Never or almost never have the symptom

1 - Occasionally have it, effect is not severe

2 - Occasionally have it, effect is severe

3 - Frequently have it, effect is not severe

4 - Frequently have it, effect is severe

HEAD	_____ Headaches	Total _____
	_____ Faintness	
	_____ Dizziness	
	_____ Insomnia	
EYES	_____ Watery or itchy eyes	Total _____
	_____ Swollen, reddened or sticky eyelids	
	_____ Bags or dark circles under eyes	
	_____ Blurred or tunnel vision (does not include near- or far-sightedness)	
EARS	_____ Itchy ears	Total _____
	_____ Earaches, ear infections	
	_____ Drainage from ear	
	_____ Ringing in ears, hearing loss	
NOSE	_____ Stuffy nose	Total _____
	_____ Sinus problems	
	_____ Hay fever	
	_____ Sneezing attacks	
	_____ Excessive mucus formation	
MOUTH/THROAT	_____ Chronic coughing	Total _____
	_____ Gagging, frequent need to clear throat	
	_____ Sore throat, hoarseness, loss of voice	
	_____ Swollen or discolored tongue, gums, lips	
	_____ Canker sores	
SKIN	_____ Acne	Total _____
	_____ Hives, rashes, dry skin	
	_____ Hair loss	
	_____ Flushing, hot flashes	
	_____ Excessive sweating	
HEART	_____ Irregular or skipped heartbeat	Total _____
	_____ Rapid or pounding heartbeat	
	_____ Chest pain	

LUNGS	_____ Chest congestion	Total _____
	_____ Asthma, bronchitis	
	_____ Shortness of breath	
	_____ Difficulty breathing	
DIGESTIVE TRACT	_____ Nausea, vomiting	Total _____
	_____ Diarrhea	
	_____ Constipation	
	_____ Bloating feeling	
	_____ Belching, passing gas	
	_____ Heartburn	
	_____ Intestinal/stomach pain	
JOINTS/MUSCLE	_____ Pain or aches in joints	Total _____
	_____ Arthritis	
	_____ Stiffness or limitation of movement	
	_____ Pain or aches in muscles	
	_____ Feeling of weakness or tiredness	
WEIGHT	_____ Binge eating/drinking	Total _____
	_____ Craving certain foods	
	_____ Excessive weight	
	_____ Compulsive eating	
	_____ Water retention	
	_____ Underweight	
ENERGY/ACTIVITY	_____ Fatigue, sluggishness	Total _____
	_____ Apathy, lethargy	
	_____ Hyperactivity	
	_____ Restlessness	
MIND	_____ Poor memory	Total _____
	_____ Confusion, poor comprehension	
	_____ Poor concentration	
	_____ Poor physical coordination	
	_____ Difficulty in making decisions	
	_____ Stuttering or stammering	
	_____ Slurred speech	
	_____ Learning disabilities	
EMOTIONS	_____ Mood swings	Total _____
	_____ Anxiety, fear, nervousness	
	_____ Anger, irritability, aggressiveness	
	_____ Depression	
OTHER	_____ Frequent illness	Total _____
	_____ Frequent or urgent urination	
	_____ Genital itch or discharge	
GRAND TOTAL		_____

Life Stress Questionnaire

Name _____

Date _____

During the past two years, have you had any of the following things happen to you? If so, simply circle one of the numbers following those items (and only those items that apply to you). Circle only one number after each event which has occurred in your life recently.

LIFE EVENT		POINT VALUE		
		Slight	Moderate	Great
Example:	Change in social activities	10	15	20
	Change in sleeping habits	10	15	20
	Change in residence	10	15	20
1	Change in social activities	10	15	20
2	Change in sleeping habits	10	15	20
3	Change in residence	10	20	30
4	Change in work hours	15	20	25
5	Change in church activities	15	20	25
6	Tension at work	20	25	30
7	Small children in the home	20	25	30
8	Change in living conditions	20	25	30
9	Outstanding personal achievement	25	30	35
10	Problem teenager(s) in the home	25	30	35
11	Trouble with in-laws	25	30	35
12	Difficulties with peer group	25	30	35
13	Son or daughter leaving home	25	30	35
14	Change in responsibilities at work	25	30	35
15	Taking over a major financial responsibility	25	30	35
16	Foreclosure of mortgage or loan	25	30	40
17	Change in relationship with spouse	30	35	40
18	Change to different line of work	30	35	40
19	Loss of a close friend	30	35	45
20	Gain of a new family member	35	40	45
21	Sex difficulties	35	40	45
22	Pregnancy	35	40	50
23	Change in health of family member	40	45	50
24	Retirement	40	45	55
25	Loss of job	45	50	55
26	Change in quality of religious faith	45	50	55
27	Marriage	45	50	55
28	Personal injury or illness	45	50	65
29	Loss of self-confidence	55	60	70
30	Death of a close family member	50	60	70
31	Injury to reputation	50	60	75
32	Trouble with the law	55	65	75
33	Marital separation	55	65	85
34	Divorce	65	76	120
35	Death of spouse	80	100	
36	Other (invalid in family; drug or alcohol problem, etc.)	_____	_____	_____
37	Other: _____	_____	_____	_____
Total of three columns		_____	_____	_____

Scoring System

- (1) Greater than 300, highly significant life stress
- (2) 200–300, significant life stress
- (3) 150–200, moderate life stress
- (4) Less than 150, low life stress

Nutrient Deficiency Signs and Symptoms

By Nutrient:

Vitamin A	
Face	Acne, dermatitis (dry, scaly skin), follicular hyperkeratosis
Eyes	Photophobia; poor twilight vision; loss of shiny, bright, moist appearance of eyes; xerosis of bulbar conjunctivas; loss of light reflex; decreased lacrimation; keratomalacia (corneal softening); corneal ulceration which may lead to extrusion of lens; Bitot's spots (frothy white or yellow spots under bulbar conjunctivas); conjunctival xerosis; corneal xerosis
Mouth	Gingivitis
Throat	Enlarged tonsils in a child
Skin	Dry skin (xerosis); rough, bumpy skin on back of arms; psoriasis; erythema early, vascularization, crusting, desquamation; increased pigmentation (even in black people), thickened, inelastic, fissured, especially in skin exposed to sun; becoming scaly, dry, atrophic in intertriginous areas, maceration and abrasion may occur; Casal's necklace in neckline exposed to sun; malar and supraorbital pigmentation; impaired wound healing
Skeletal	Bone/joint pain
Vitamin B12	
Face	Yellow face
Eyes	Optic neuritis
Mouth	Angular stomatitis
Tongue	Geographic tongue; sore, reddened tongue; filiform papillary atrophy; glossitis
Skin	Hyperpigmentation; pallor, icterus; rough, bumpy skin on back of arm
Circulation	Anemia, megaloblastic
Nervous System	Ataxia, with loss of ankle knee reflexes; peripheral neuropathy; paresthesia; areflexia, extensor plantar responses, loss of position and vibratory sense, ataxia, paresthesia; psychotic behavior (dementia); wide-based gait
Vitamin B6	
Mouth	Angular stomatitis
Tongue	Sore, reddened tongue
Lips	Cheilosis, inflammation of the mucus membranes of the lips, loss of clear differentiation between mucocutaneous border
Skin	Seborrheic-like dermatitis; skin deterioration; rough, bumpy skin on back of arm

Hands/Fingers/Fingernails	Tender lumps on finger end joints
Nervous system	Peripheral neuropathy; tremors, convulsions, behavioral disturbances; slow mentation, mental depression
Riboflavin	
Eyes	Circumcorneal capillary injection with penetration of corneal limbus; red and moist tissue at external angles of both eyes; angular blepharitis (or palpebritis); conjunctival xerosis
Mouth	Gums, periodontal problems; angular stomatitis; gingivitis
Tongue	Sore, reddened tongue; filiform papillary atrophy; glossitis
Lips	Cheilosis, inflammation of the mucus membranes of the lips, loss of clear differentiation between mucocutaneous border
Nose	Nasolabial dyssebacea (exfoliation, inflammation, excessive oil production, fissuring of sebaceous glands, which are moist and red)
Skin	Decreased skin-hair-nail turgor; seborrheic-like dermatitis
Niacin	
Mouth	Gingival tenderness; gingivitis; angular stomatitis
Tongue	Sore, reddened tongue; filiform papillary atrophy; glossitis; tongue fissuring; halitosis
Lips	Cheilosis, inflammation of the mucus membranes of the lips, loss of clear differentiation between mucocutaneous border
Skin	Dermatitis, hyperpigmentation; erythema early, vascularization, crusting, desquamation; increased pigmentation (even in black people), thickened, inelastic, fissured, especially in skin exposed to sun; becoming scaly, dry, atrophic in intertriginous areas, maceration and abrasion may occur; Casal's necklace in neckline exposed to sun; malar and supraorbital pigmentation; scrotum dermatitis, erythema, hyperpigmentation; pellagrous dermatosis
Hands/Fingers/Fingernails	Onycholysis
Gastrointestinal Tract	Diarrhea
Nervous System	Psychotic behavior (dementia); acute disorientation
Thiamine	
Throat	Parotid enlargement
Muscular	Muscle pain; calf muscle tenderness, weakness
Cardiovascular	Tachycardia, cardiac enlargement, congestive heart failure (high-output type); palpitations, arrhythmia; cardiomegaly
Circulation	Intermittent claudication

Nervous System	Ataxia, with loss of ankle knee reflexes; peripheral neuropathy; paresthesia; loss of proprioception; hyporeflexia, foot and wrist drop; hypesthesia; paresthesia; psychotic behavior (dementia); nystagmus; ophthalmoplegia; wide-based gait; peripheral edema; somatic wasting
Niacinamide	
Hands /Fingers/ Fingernails	Slightly swollen and painful PIP joints (osteoarthritis); painful, swollen MCP joints, as well as wrists and other joints (rheumatoid arthritis); tender lumps on fingers and joints
Vitamin C	
Mouth	Gums, periodontal problems; herpes; reddened gumline without margination; ecchymotic-like lesions; interdental gingival hypertrophy
Throat	Enlarged tonsils in a child
Skin	Perifollicular petechiae that produce a "pink-halo" effect around coiled hair follicles, intradermal petechiae (purpura, ecchymoses due to capillary fragility), hemarthroses (cortical hemorrhages of bone visualizable on X-ray); impaired wound healing
Hair	Corkscrew, "swan neck" deformity
Hands/Fingers/Fingernails	Splinter hemorrhages
Skeletal	Bone/joint pain; subperiosteal hematoma, epiphyseal enlargement (painful)
Muscular	Intramuscular hematoma
General	Easy bruising
Vitamin D	
Mouth	Gums, periodontal problems
Hands/Fingers/Fingernails	Psoriatic nails
Skeletal	Epiphyseal enlargement (painless), beading of ribs ("rachitic rosary"), delayed fusion of fontanelles, craniotabes (abnormal softening of the skull bones), bowed legs, frontal or parietal bossing of skull, deformities of thorax (Harrison's sulcus, pigeon breast), osteomalacia, osteoporosis, rickets; bone/joint pain; bone tenderness
Muscular	Hypotonia; myofascial back pain; decreased grip strength
Cardiovascular	Hypertension
General	Tetany and muscle cramps
Vitamin E	
Eyes	Retinal field defect
Circulation	Anemia, hemolytic
Nervous System	Ataxia, with loss of ankle knee reflexes; peripheral neuropathy

Vitamin K	
Skin	Perifollicular petechiae that produce a "pink-halo" effect around coiled hair follicles, intradermal petechiae (purpura, ecchymoses due to capillary fragility), hemarthroses (cortical hemorrhages of bone visualizable on X-ray); intracutaneous hemorrhages, GI hemorrhage
Mouth	Ecchymotic-like lesions
Circulation	Prolonged clotting time
Cardiovascular	Palpitations, arrhythmia
General	Easy bruising
Biotin	
Tongue	Sore, reddened tongue
Skin	Dry skin (xerosis); seborrheic-like dermatitis
Hair	Thin, sparse distribution; hair becomes fine, dull, dry, brittle, stiff, straight; becomes red in black people, then lighter in color; may be "bleached" in white people ("flag sign"); can be plucked easily and painlessly
Nervous System	Slow mentation, mental depression
Copper	
Hair	Menkes steely hair
Hands/Fingers/Fingernails	Fingernails that are ridging, brittle, easily broken, flattened, spoon-shaped, thin, lusterless, Beau's lines, Muehrcke's lines
Circulation	Anemia, microcytic hypochromic
Calcium	
Teeth	Mottled enamel, fluorosis
Hands/Fingers/Fingernails	Fingernails that are weak, thin, bend easily, frequently crack and chip
Skeletal	Epiphyseal enlargement (painless), beading of ribs ("rachitic rosary"), delayed fusion of fontanelles, craniotabes (abnormal softening of the skull bones), bowed legs, frontal or parietal bossing of skull, deformities of thorax (Harrison's sulcus, pigeon breast), osteomalacia, osteoporosis, rickets
Cardiovascular	Hypertension; palpitations, arrhythmia
Nervous System	Paresthesias about the lips, tongue, fingers; carpopedal spasm
General	Tetany and muscle cramps

Folate/Folic Acid	
Eyes	Pale palpebral conjunctivas
Mouth	Gums, periodontal problems; aphthous stomatitis
Tongue	Geographic tongue; sore, reddened tongue; filiform papillary atrophy; glossitis
Skin	Hyperpigmentation; pallor, icterus
Circulation	Anemia, megaloblastic
Nervous System	Psychotic behavior (dementia)
Fluoride	
Teeth	Caries
Iodine	
Throat	Neck mass (goiter)
Nervous System	Hyporeflexia, foot and wrist drop, hypesthesia, paresthesia
Iron	
Face	Pale tongue, cheeks, and conjunctives
Eyes	Pale palpebral conjunctivas
Mouth	Angular stomatitis
Tongue	Filiform papillary atrophy; glossitis
Skin	Pallor, icterus
Hands/Fingers/Fingernails	Fingernails that are ridging, brittle, easily broken, flattened, spoon-shaped, thin, lusterless, Beau's lines, Muehrcke's lines; onycholysis; pale nail beds
Circulation	Anemia microcytic hypochromic
Gastrointestinal Tract	Plummer Vinson syndrome
Pyridoxine	
Eyes	Angular blepharitis (or palpebritis)
Tongue	Glossitis
Nose	Nasolabial seborrhea
Nervous System	Peripheral neuropathy, symmetrical sensory and motor deficits, especially in lower extremities; drug-resistant convulsions (infants); dementia, forgetfulness

Selenium

Face	Acne
Mouth	Cold sores
Cardiovascular	Cardiomegaly

Zinc

Face	Acne; dermatitis (dry, scaly skin), follicular hyperkeratosis
Eyes	Photophobia; poor twilight vision; loss of shiny, bright, moist appearance of eyes; xerosis of bulbar conjunctivas; loss of light reflex; decreased lacrimation; keratomalacia (corneal softening); corneal ulceration which may lead to extrusion of lens; Bitot's spots (frothy white or yellow spots under bulbar conjunctivas)
Mouth	Angular stomatitis
Tongue	Geographic tongue; hypogeusia (diminished taste acuity)
Throat	Enlarged tonsils in a child
Skin	Acne on back, chest, face, and shoulders; dry skin (xerosis); psoriasis; seborrheic-like dermatitis; erythema early, vascularization, crusting, desquamation; increased pigmentation (even in black people), thickened, inelastic, fissured, especially in skin exposed to sun; becoming scaly, dry, atrophic in intertriginous areas, maceration and abrasion may occur; Casal's necklace in neckline exposed to sun; malar and supraorbital pigmentation; impaired wound healing
Hair	Thin, sparse distribution; hair becomes fine, dull, dry, brittle, stiff, straight; becomes red in black people, then lighter in color; may be "bleached" in white people ("flag sign"); can be plucked easily and painlessly
Hands/Fingers/Fingernails	Cracks and splitting of skin on fingertips; fingernails that are weak, thin, bend easily, frequently crack and chip; white pitting (leukonychia); fingernails that are ridging, brittle, easily broken, flattened, spoon-shaped, thin, lusterless, Beau's lines, Muehrcke's lines; chronic paronychia; white spots on fingernails
Gastrointestinal Tract	Diarrhea
General	Somatic wasting

Essential Fatty Acids

Face	Acne; dermatitis (dry, scaly skin), follicular hyperkeratosis
Eyes	Reduced visual acuity
Nose	Nasolabial seborrhea
Skin	Acne on back, chest, face, and shoulders (omega-3); dry skin (xerosis); rough, bumpy skin on back of arm; dermatitis; eczema; lackluster skin (omega-3); thick calluses (omega-3); impaired wound healing (omega-6); oily/combo skin (omega-3)
Hair	Dry hair, dandruff

Hands/Fingers/Fingernails	Cracks and splitting of skin on fingertips; fingernails that are weak, thin, bend easily, frequently crack and chip
Nervous System	Paresthesia (omega-3); weakness, inability to walk (omega-3); neuropathy
General	Decreased memory and mental abilities, psychological disturbances; thirst, polydipsia, polyuria
Protein	
Face	Brown, patchy pigmentation of cheeks, parotid enlargement, and "moon face" (calorie)
Mouth	Reddened gumline without margination (energy)
Teeth	Malposition, hypoplastic line across upper primary incisors, becomes filled with yellow-brown pigment, caries then occurs and tooth may break off (calorie)
Skin	Impaired wound healing (calorie)
Hair	Thin, sparse distribution (energy); dry, dull, depigmented; hair becomes fine, dull, dry, brittle, stiff, straight; becomes red in black people, then lighter in color; may be "bleached" in white people ("flag sign"); can be plucked easily and painlessly (calorie)
Hands/Fingers/Fingernails	Transverse depigmentation; fingernails that are ridged, brittle, easily broken, flattened, spoon-shaped, thin, lusterless, Beau's lines, Muehrcke's lines
Gastrointestinal Tract	Ascites; hepatomegaly
Muscular	Atrophic muscles; decreased grip strength
General	Peripheral edema, muscle wasting (calorie)
Fat	
Gastrointestinal Tract	Hepatomegaly
General	Reduced subcutaneous fat as evidenced by well-demarcated bony prominences and veins, loss of gluteal and perianal fat
Coenzyme Q10	
Mouth	Gums, periodontal problems
Cardiovascular	Tachycardia, cardiac enlargement, congestive heart failure (high-output type); palpitations, arrhythmia
Lysine	
Mouth	Herpes
Flavonoids	
Mouth	Herpes

Phosphorus	
Teeth	Caries
Nervous System	Acute disorientation; circumoral and extremity paresthesias
Nickel	
Skin	Psoriasis
Bromide	
Skin	Psoriasis
Manganese	
Hair	Dry, dull, sparse, depigmented
Glucosamine Sulfate and Chondroitin	
Hands/Fingers/Fingernails	Slightly swollen and painful PIP joints (osteoarthritis)
Eicosatetraenoic Acids	
Hands/Fingers/Fingernails	Painful, swollen MCP joints, as well as wrists and other joints (rheumatoid arthritis)
Cetyl Myristoleic Acid	
Hands/Fingers/Fingernails	Painful, swollen MCP joints, as well as wrists and other joints (rheumatoid arthritis)
Magnesium	
Respiratory	Reactive airways
Muscular	Spasm
Cardiovascular	Hypertension; palpitations, arrhythmia
Nervous System	Tremor, convulsions, behavioral disturbances; carpopedal spasm
Potassium	
Gastrointestinal Tract	Ileus
Cardiovascular	Hypertension
General	Tetany and muscle cramps
Linolenic Acid	
Skin	Dry skin (xerosis); seborrheic-like dermatitis

Nutrient Deficiency Signs and Symptoms, continued

By Physical Exam Finding:	Potential Association with Nutrient Deficiency/Insufficiency or Allergen:
Face	
Acne	Zinc Allergy (eliminate refined foods/sugars) Vitamin A Essential fatty acids Selenium
Pale tongue, cheeks, and conjunctivas	Anemia (iron deficient)
Brown, patchy pigmentation of cheeks, parotid enlargement, and "moon face"	Protein-calorie
Reddened facial skin, especially on forehead and cheeks, often with scattered medium to large acne-like lumps (i.e., acne rosacea)	Low stomach acid and pepsin production
Red face (rosacea)	Food allergy, yeast, skin mites allergy
Flushing	Allergy (e.g., red ears)
Yellow face	Vitamin B12
Dermatitis (dry, scaly skin), follicular hyperkeratosis	Essential fatty acids, vitamin A, zinc
Eyes	
Dilated pupils	Allergy (especially milk)
Photophobia; poor twilight vision; loss of shiny, bright, moist appearance of eyes; xerosis of bulbar conjunctivas; loss of light reflex; decreased lacrimation; keratomalacia (corneal softening); corneal ulceration which may lead to extrusion of lens; Bitot's spots (frothy white or yellow spots under bulbar conjunctivas)	Vitamin A, zinc
Pale palpebral conjunctivas	Iron or folate
Circumcorneal capillary injection with penetration of corneal limbus	Riboflavin
Red and moist tissue at external angles of both eyes	Riboflavin
Angular blepharitis (or palpebritis)	Pyridoxine, riboflavin
Optic neuritis	Vitamin B12
Conjunctival xerosis	Vitamin A, riboflavin
Corneal xerosis	Vitamin A
Dark under-eye circles (allergic shiners)	Allergy (food or other)

Retinal field defect	Vitamin E
Reduced visual acuity	Essential fatty acids
Mouth	
Canker sore (aphthous ulcer)	Food allergy(ies) Toothpaste with sodium lauryl sulfate can cause recurrences
Aphthous stomatitis	Folic acid
Cold sores	Selenium
Gums; periodontal problems	Coenzyme Q10, folate "mouthwash," vitamin C, riboflavin, vitamin D
Gingival tenderness	Niacin
Herpes	Lysine, vitamin C, flavonoids
Reddened gumline without margination	Vitamin C
Ecchymotic-like lesions	Vitamins C and K, protein-energy
Angular stomatitis	Riboflavin, niacin, other B vitamins, iron, zinc
Interdental gingival hypertrophy	Vitamin C
Gingivitis	Vitamin A, niacin, riboflavin
Tongue	
Geographic tongue	Folate Vitamin B12 Zinc Genetic and unchangeable
Sore, reddened tongue	Niacin, folate, vitamins B12 and B6, biotin, riboflavin
Filiform papillary atrophy	Niacin, iron, folate, vitamin B12, riboflavin
Glossitis	Riboflavin, folic acid, pyridoxine, niacin, vitamin B12, iron
Hypogeusia (diminished taste acuity)	Zinc
Teeth indentations on tongue	Food allergy(ies)
Tongue fissuring	Niacin
Halitosis	Niacin

Lips	
Cheilosis, inflammation of the mucus membranes of the lips, loss of clear differentiation between mucocutaneous border	Riboflavin, vitamin B6, niacin
Teeth	
Caries	Fluoride, phosphorus
Mottled enamel, fluorosis	Fluoride (excessive), calcium
Malposition, hypoplastic line across upper primary incisors, becomes filled with yellow-brown pigment, caries then occurs and tooth may break off	Protein-calorie
Nose	
Polyps in the nose	Allergy (very likely salicylate sensitive)
Nasolabial dyssebacea (exfoliation, inflammation, excessive oil production, fissuring of sebaceous glands, which are moist and red)	Riboflavin
Nasolabial seborrhea	Pyridoxine, essential fatty acids
Throat	
Enlarged tonsils in a child	Food allergy(ies) Vitamin A Vitamin C Zinc
Swollen lymph nodes in neck	Food allergy(ies)
Parotid enlargement	Thiamin
Neck mass (goiter)	Iodine
Skin	
Acne (back, chest, face, shoulders)	High-dose vitamin A, zinc, omega-3 oils
Dry skin (xerosis)	Essential fatty acids, vitamin A, biotin, linolenic acid, zinc
Skin surface slightly yellow	Beta-carotene (excessive)
Rough, bumpy skin on back of arm	Vitamin A Essential fatty acids B vitamins Pancreatic enzymes to aid absorption of essential fatty acids, vitamin A, carotene
Psoriasis	Nickel, bromide, vitamin A, zinc

Perifollicular petechiae that produce a "pink-halo" effect around coiled hair follicles, intradermal petechiae (purpura, ecchymoses due to capillary fragility), hemarthroses (cortical hemorrhages of bone visualizable on X-ray)	Vitamin C, vitamin K
Decreased skin-hair-nail turgor	Riboflavin
Dermatitis	Niacin, essential fatty acids
Seborrheic-like dermatitis	Riboflavin, vitamin B6, biotin, zinc, linoleic acid
Skin deterioration	Vitamin B6
Hyperpigmentation	Folate, vitamin B12, niacin
Intracutaneous hemorrhages, GI hemorrhage	Vitamin K
Pallor, icterus	Iron, folic acid, vitamin B12
Erythema early, vascularization, crusting, desquamation; increased pigmentation (even in black people), thickened, inelastic, fissured, especially in skin exposed to sun; becoming scaly, dry, atrophic in intertriginous areas, maceration and abrasion may occur; Casal's necklace in neckline exposed to sun; malar and supraorbital pigmentation	Niacin, vitamin A, zinc
Scrotum dermatitis, erythema, hyperpigmentation	Niacin
Eczema	Allergy Fatty acids
Itching: anus, arms, ear canals, eyes, feet, hands, legs, nipples, nose, penis, roof of mouth, scalp, skin in general, throat	Allergy
Lackluster skin	Omega-3 oils
Thick calluses	Omega-3 oils
Bumps on back of upper arms	Omega-3 oils; could also be vitamin A responsive; sometimes a weird expression of eczema
Pellagrous dermatosis	Niacin
Impaired wound healing	Vitamin C, vitamin A, zinc, protein, omega-6 essential fatty acids
Oily skin (also what TV used to call combination skin)	Omega-3 oils
Hair	
Thinning hair on arms, legs, pubic area of older females	DHEA
Thin, sparse distribution	Protein-energy, biotin, zinc
Corkscrew, "swan neck" deformity	Vitamin C
Dry, dull, sparse, depigmented	Protein, manganese

Hair becomes fine, dull, dry, brittle, stiff, straight; becomes red in black people, then lighter in color; may be "bleached" in white people ("flag sign"); can be plucked easily and painlessly	Protein-calorie, zinc, biotin
Menkes steely hair	Copper
Dry hair, dandruff	Essential fatty acids
Hands/Fingers/Fingernails	
Cracks and splitting of skin on fingertips	Zinc, essential fatty acids
Slightly swollen and painful PIP joints (osteoarthritis)	Glucosamine sulfate and chondroitin Niacinamide "Nightshade" vegetable allergies
Painful, swollen MCP joints, as well as wrists and other joints (rheumatoid arthritis)	Food allergy(ies) Niacinamide Eicosatetraenoic acids Cetyl myristoleic acid
Tender lumps on finger end joints	Niacinamide, vitamin B6
Fingernails that are weak, thin, bend easily, frequently crack and chip	Underfunctioning stomach (low acid, low pepsin) Essential fatty acid Calcium Zinc
Transverse depigmentation	Protein
White pitting (leukonychia)	Zinc
Psoriatic nails	Vitamin D
Fingernails that are ridging, brittle, easily broken, flattened, spoon-shaped, thin, lusterless, Beau's lines, Muehrcke's lines	Iron, copper, zinc, protein
Onycholysis	Iron, niacin
Chronic paronychia	Zinc
Splinter hemorrhages	Vitamin C
Pale nail beds	Iron
White spots on fingernails	Zinc
Skeletal	
Epiphyseal enlargement (painless), beading of ribs ("rachitic rosary"), delayed fusion of fontanelles, craniotabes (abnormal softening of the skull bones), bowed legs, frontal or parietal bossing of skull, deformities of thorax (Harrison's sulcus, pigeon breast), osteomalacia, osteoporosis, rickets	Vitamin D, calcium
Bone/joint pain	Vitamin A, vitamin D, vitamin C

Bone tenderness	Vitamin D
Subperiosteal hematoma, epiphyseal enlargement (painful)	Vitamin C
Respiratory	
Reactive airways	Magnesium
Circulation	
Anemia, hemolytic	Vitamin E
Anemia, microcytic hypochromic	Copper, iron
Anemia, megaloblastic	Folate, vitamin B12
Prolonged clotting time	Vitamin K
Intermittent claudication	Thiamin
Gastrointestinal Tract	
Ascites	Protein
Hepatomegaly	Protein, fat
Diarrhea	Zinc, niacin, dysbiosis
Ileus	Potassium
Plummer Vinson syndrome	Iron
Muscular	
Hypotonia	Vitamin D
Muscle pain	Thiamin
Intramuscular hematoma	Vitamin C
Calf muscle tenderness, weakness	Thiamin
Atrophic muscles	Protein
Myofascial back pain	Vitamin D
Decreased grip strength	Protein, vitamin D
Spasm	Magnesium

Cardiovascular	
Tachycardia, cardiac enlargement, congestive heart failure (high-output type)	Thiamine, coenzyme Q10
Hypertension	Calcium, potassium, magnesium, vitamin D
Palpitations, arrhythmia	Thiamine, magnesium, coenzyme Q10, vitamin K, calcium
Cardiomegaly	Selenium, thiamin
Nervous System	
Ataxia, with loss of ankle knee reflexes	Thiamin, vitamin E, vitamin B12
Peripheral neuropathy	Thiamin, vitamin B6, vitamin E, vitamin B12
Peripheral neuropathy, symmetrical sensory and motor deficits, especially in lower extremities; drug-resistant convulsions (infants); dementia, forgetfulness	Pyridoxine
Paresthesia	Thiamin, vitamin B12, omega-3 essential fatty acids
Loss of proprioception	Thiamin
Hyporeflexia, foot and wrist drop, hypesthesia, paresthesia	Thiamin, iodine
Areflexia, extensor plantar responses, loss of position and vibratory sense, ataxia, paresthesia	Vitamin B12
Paresthesias about the lips, tongue, fingers	Calcium
Tremor, convulsions, behavioral disturbances	Magnesium, vitamin B6
Psychotic behavior (dementia)	Niacin, thiamin, vitamin B12, folate
Acute disorientation	Phosphorus, niacin
Nystagmus	Thiamin
Ophthalmoplegia	Thiamin
Wide-based gait	Thiamin, vitamin B12
Weakness, inability to walk	Omega-3 fatty acids
Carpopedal spasm	Calcium, magnesium
Circumoral and extremity paresthesias	Phosphorus
Slow mentation, mental depression	Biotin, vitamin B6
Neuropathy	Essential fatty acids

General	
Peripheral edema	Protein, thiamin
Muscle wasting	Protein, calorie
Somatic wasting	Thiamin, zinc
Reduced subcutaneous fat as evidenced by well-demarcated bony prominences and veins, loss of gluteal and perianal fat	Fat
Decreased memory and mental abilities, psychological disturbances	Essential fatty acids
Thirst, polydipsia, polyuria	Essential fatty acids
Tetany and muscle cramps	Vitamin D, magnesium, calcium, potassium
Red ears	Allergy (food or other)
Easy bruising	Allergy (food or other), often yeast, vitamin K, vitamin C
Swollen ankles and feet	Allergy vs. the obvious cardiac/renal problems

Three-Day Diet Diary

Please complete this Three-Day Diet Diary for three consecutive days within a week before your scheduled visit. Please include one weekend day.

- Record information as soon as possible after the food has been consumed.
- Describe the food or beverage consumed e.g., milk—whole, 2%, or nonfat; toast—whole wheat, white, buttered; chicken—fried, baked, breaded,

etc. Record the amount of each food consumed using standard measurements as much as possible, such as 8 ounces, 1/2 cup, 1 teaspoon, etc.

- Include any added items. For example: tea with 1 teaspoon sugar, potato with 2 teaspoons butter, etc.
- Please record all beverages, including water. List them in the “Beverage” category.

Diet Diary

Name: _____ Date: _____

Time	Food	Amount	Time	Beverage	Amount

Glossary

Antecedents: factors that predispose to acute or chronic illness. For a person who is ill, antecedents form the illness diathesis. From the perspective of prevention, they are risk factors. Examples of genetic antecedents include the breast cancer risk genes BRCA1 and BRCA2.

Biochemical individuality: the idea that each individual has a unique physiological and biochemical composition, based upon the interactions of his or her individual genetic make-up with the environment—i.e., the continuous exposure to “inputs” (diet, experiences, beliefs, activity, toxins, medications, etc.) that influences our genes. It is this combination of factors that accounts for the endless variety of phenotypic responses seen every day by clinicians. The unique makeup of each individual requires personalized levels of nutrition and a lifestyle adapted to that individual’s needs in order to achieve optimal health. The consequences of not meeting the specific needs of the individual are expressed, over time, as degenerative disease.

Biomarker: a substance used as an indicator of a biological state. Such characteristics are objectively measured and evaluated as indicators of normal biological processes, pathogenic processes, or pharmacologic responses to a therapeutic intervention. Cancer biomarkers include prostate specific antigen (PSA) and carcinoembryonic antigen (CEA).

Biotransformation: the modification(s) of a chemical compound made by an organism. Such compounds include, but are not limited to, nutrients, amino acids, toxins, heavy metals, or drugs in the body. Biotransformation also renders nonpolar compounds polar so that they are excreted, not reabsorbed in renal tubules.

Functional medicine: a systems-based, science-driven approach to individualized medicine that focuses on uncovering the underlying causes of disease and dysfunction rather than on treatment of symptoms.

Functional Medicine Matrix: the graphic representation of the functional medicine approach, displaying the seven fundamental clinical imbalances, the patient’s

known antecedents, triggers, and mediators, and the salutogenic factors that promote health. Practitioners can use the matrix to help organize their thoughts and observations about the patient’s health and decide how to focus therapeutic and preventive strategies.

Core Clinical Imbalances: The foundational principles of how the human organism functions—and how its systems communicate and interact—are essential to the process of linking ideas about multifactorial causation with the perceptible effects we call disease or dysfunction. To assist clinicians in this process, functional medicine has identified and organized a set of core clinical imbalances that are linked to fundamental physiological processes. They serve to marry the mechanisms of disease with the manifestations and diagnoses of disease. Many common underlying pathways of disease are reflected in these clinical imbalances:

Communication Imbalances

- Endocrine
- Neurotransmitter
- Immune messengers
- Cognition

Energy Imbalances

- Energy regulation
- Mitochondrial function

Defense and Repair Imbalances

- Immune system
- Inflammatory processes
- Infection and microbiota

Assimilation Imbalances

- Digestion
- Absorption
- Microbiota/GI
- Respiration

Structural Integrity Imbalances

- From the subcellular membranes
- To the musculoskeletal system

Biotransformation and Elimination Imbalances

- Toxicity
- Detoxification

Using this construct, it becomes much clearer that one disease/condition may have multiple causes (i.e., multiple clinical imbalances), just as one fundamental imbalance may be at the root of many seemingly disparate conditions

Cytokines: immunoregulatory proteins (such as interleukin, tumor necrosis factor, and interferon). They may act locally or systemically and tend to have both immunomodulatory and other effects on cellular processes in the body. Cytokines have been used in the treatment of certain cancers.

Genomics: the study of the whole genome of organisms, including interactions between loci and alleles within the genome. Research on single genes does not fall into the definition of genomics unless the aim of this functional information analysis is to elucidate the gene's effect on the entire genome network. Genomics may also be defined as the study of all the genes of a cell, or tissue, at the DNA (genotype), mRNA (transcriptome), or protein (proteome) levels.

Glucosinolates: a class of organic compounds that contain sulfur and nitrogen and are derived from glucose and an amino acid. They occur as secondary metabolites of almost all plants of the order Brassicales. Glucosinolates have toxic effects in both humans and animals at high doses (mainly as goitrogens) but, at subtoxic doses, their hydrolytic and metabolic products may act as chemoprotective agents against chemically-induced carcinogens by blocking the initiation of tumors in a variety of tissues.

Homeostasis and homeodynamics: The former term describes the tendency of living things to maintain physiological parameters within a narrow range usually considered "normal" in order to maintain optimal function. Under this definition, disease can be defined as a departure from the homeostatic state. The latter term describes the tendency of homeostatic set points to change throughout an organism's lifespan, and thus describes how departures from a homeostatic norm can

be adaptive (e.g., fever) or pathological, depending on the context.

Isoflavones: a class of polyphenolic, antioxidant, organic compounds, often naturally occurring, related to the isoflavonoids, many of which act as phytoestrogens in mammals. Some isoflavones and isoflavone-rich foods are purported to possess activity against cancer, including certain types of breast and prostate cancer. Isoflavones are produced almost exclusively by members of the Fabaceae/Leguminosae (bean) family, such as soybeans.

Long latency disease: disease that becomes manifest at a time remote from the initial exposure to disease triggers, or diseases requiring continued exposure to triggers and mediators over an extended period of time to manifest frank pathology. Examples include heart disease, cancer, and osteoporosis.

Mediators: intermediaries that contribute to the continued manifestations of disease. Mediators do not "cause" disease; instead, they underlie the host response to triggers. Examples include biochemical factors (e.g., cytokines and leukotrienes) as well as psychosocial ones (e.g., reinforcement for staying ill).

Metabolomics (or metabonomics): "The study of metabolic responses to drugs, environmental changes and diseases. Metabonomics is an extension of genomics (concerned with DNA) and proteomics (concerned with proteins). Following on the heels of genomics and proteomics, metabonomics may lead to more efficient drug discovery and individualized patient treatment with drugs, among other things." (From MedicineNet.com)

Nutrigenomics (or nutritional genomics): the study of how different foods may interact with specific genes to increase the risk of common chronic diseases such as type 2 diabetes, obesity, heart disease, stroke, and certain cancers. It can also be described as the study of the influence of genetic variation on nutrition by correlating gene expression or single-nucleotide polymorphisms with a nutrient's absorption, metabolism, elimination or biological effects. Nutrigenomics also seeks to provide a molecular understanding of how common chemicals in the diet affect health by altering the expression of genes and the structure of an individ-

ual's genome. The ultimate aim of nutrigenomics is to develop rational means to optimize nutrition, with respect to the subject's genotype.

Organ reserve: The difference between the maximal function of a vital organ and the level of function required to maintain an individual's daily life. In other words, it is the "reserve power" of a particular organ, above and beyond what is required in a healthy individual. It can also be thought of as the degrees of freedom available in the body organs to perform their functions and maintain health. Decline in the organ reserve occurs under stress, during sickness, and as we age.

Organ system diagnosis: In the allopathic medical model, it is common to give a collection of symptoms a name based on dysfunction of an organ system, then to cite the named disease as the cause of the symptoms the patient is experiencing. This bit of circular logic avoids any discussion of the systemic or underlying causes of dysfunction and also treats all people with "disease X" the same, despite the fact that two people with the same collection of symptoms may have completely different underlying physiological causes for the symptoms they display.

Oxidation-reduction: paired chemical reactions that occur in balance with each other within the body of a healthy individual. These reactions involve the transfer of electrons (or the distribution of electron sharing) and thus require both a donor and acceptor. When this physiological parameter is out of balance, a net accumulation of donors or acceptors can lead to deleterious cellular oxidation phenomena (lipid peroxidation, free radical formation).

Precipitating event: similar to a trigger but, whereas a trigger only provokes illness as long as the person is exposed to it (or for a short while afterward), a precipitating event initiates a change in health status that persists long after the exposure ends.

Proteomics: the large-scale study of proteins, particularly their structures and functions and including how they're modified, when and where they're expressed, how they're involved in metabolic pathways, and how they interact with one another. The proteome is the entire complement of proteins, including the modifica-

tions made to a particular set of proteins, produced by an organism or system. This will vary with time and distinct requirements, or stresses, that a cell or organism undergoes. As a result, proteomics is much more complicated than genomics: an organism's genome is more or less constant, while the proteome differs from cell to cell and from time to time.

Single nucleotide polymorphism (SNP; pronounced snip): a DNA sequence variation occurring when a single nucleotide—A, T, C, or G—in the genome differs between members of a species or between paired chromosomes in an individual. Variations in the DNA sequences of humans can affect how humans develop diseases and respond to pathogens, chemicals, drugs, vaccines, and other agents. SNPs are also thought to be key factors in applying the concept of personalized medicine.

The 5Rs: A mnemonic that contains a five step process for normalizing gastrointestinal function:

1. Remove – Removing the source of the imbalance (e.g., pathogens, allergic foods) is the critical first step
2. Replace – Next replace any factors that are missing (e.g., HCL, digestive enzymes)
3. Reinoculate – Repopulate the gut with symbiotic bacteria (e.g., lactobacilli, bifidobacteria)
4. Repair – Heal damaged gut membrane using, for example, glutamine, fiber, and butyrate
5. Rebalance – Modify attitude, diet, and lifestyle of the patient to promote a healthier way of living

Triggers: Triggers are discrete entities or events that provoke disease or its symptoms (e.g., microbes). Triggers are usually insufficient in and of themselves for disease formation, however, because the health of the host and the vigor of its response to a trigger are essential elements.

Xenobiotics: chemicals which are found in an organism but which are not normally produced by or expected to be present in it. This may also include substances which are present in much higher concentrations than are usual. The term xenobiotics is very often used in the context of pollutants such as dioxins and

polychlorinated biphenyls and their effect on the biota, because xenobiotics are understood as substances foreign to an entire biological system, i.e. artificial substances, which did not exist in nature before their synthesis by humans. Exposure to several types of xenobiotics has been implicated in cancer risk.

Additional Terms Related to Cancer

Active surveillance: Formerly called “watchful waiting,” active surveillance is a treatment option for patients with apparently slow-growing tumors in which no surgery, radiation, or chemotherapy is administered. Instead, the cancer is carefully monitored for signs of progression. If symptoms develop, or if tests indicate that the cancer is growing, treatment might be warranted. Commonly used in the treatment of prostate cancer.

Angiogenesis: growth of new blood vessels. When cancer cells are dividing rapidly, they require more oxygen and nutrients than the surrounding tissue can provide. To solve this problem, the cells release angiogenesis factors that attract the growth of new blood vessels into the tumor. One avenue for cancer treatment involves administering anti-angiogenesis factors to disrupt this process.

Apoptosis: programmed cell death. As a normal part of growth and development, cells that are superfluous or that become damaged activate a cascade of intracellular processes leading to their own demise. In cancer cells, DNA damage may inactivate the apoptosis cascade, allowing mutated cells to survive and proliferate.

Cancer: a group of diseases characterized by uncontrolled growth and spread of abnormal cells, which, if not controlled, can result in death. Cancer is caused by both external factors (tobacco, infectious organisms, chemicals, and radiation) and internal factors (inherited mutations, hormones, immune conditions, and mutations that occur from metabolism), two or more of which may act together or in sequence to initiate or promote carcinogenesis. Ten or more years often pass between exposure to external factors and detectable cancer.

Cytochromes P450 (CYP 450): a large and diverse group of enzymes, most of which function to catalyze the oxidation of organic substances. They are located either in the inner membrane of mitochondria or in the endoplasmic reticulum of cells. The substrates of CYP enzymes include metabolic intermediates such as lipids, steroidal hormones, and xenobiotic substances such as drugs.

Initiation: in carcinogenesis, the series of steps required for the transformation of healthy cells into malignant ones.

Integrative oncology: an approach to cancer that makes use of all available therapies to prevent and treat malignancy. It integrates conventional cancer therapies with science-based complementary and alternative cancer treatments, as well as therapies designed to lessen the side effects of chemotherapy and radiation.

Isothiocyanates: compounds that contain the functional group $-N=C=S$. Many natural isothiocyanates from plants (also known as mustard oils) are produced by enzymatic conversion of metabolites called glucosinolates. They have been shown to inhibit carcinogenesis and tumorigenesis and are therefore useful chemopreventive agents against the development and proliferation of cancers. In some cases, they can even induce apoptosis in cells that are resistant to some currently used chemotherapeutic drugs.

Lifetime risk: the probability that an individual, over the course of a lifetime, will develop or die from cancer. In the US, men have slightly less than a 1 in 2 lifetime risk of developing cancer; for women, the risk is a little more than 1 in 3.

Progression: an increase in the size of a tumor or the spread of cancer in the body.

Relative risk: a measure of the strength of the relationship between risk factors and a particular cancer. It compares the risk of developing cancer in persons with a certain exposure or trait to the risk in persons who do not have this characteristic. For example, male smokers are about 23 times more likely to develop lung cancer than nonsmokers, so their relative risk is 23. Most relative risks are not this large. For example, women who

have a first-degree relative (mother, sister, or daughter) with a history of breast cancer have about twice the risk of developing breast cancer compared to women who do not have this family history.

Survivorship: In cancer, survivorship covers the physical, psychosocial, and economic issues of cancer, from diagnosis until the end of life. It includes issues related to the ability to get health care and follow up treatment, late effects of treatment, second cancers, and quality of life.

21ST CENTURY MEDICINE:

*A New Model for Medical
Education and Practice*

Preface

Beginning a Journey of Discovery

The document you are about to read emerged from a systematic process of inquiry and intentionality about some of the most critical issues in health care today. While there are many vital structural factors to be addressed elsewhere (reimbursement practices, insurance coverage, electronic medical records, the medical home concept), our attention and expertise are here focused on the content and process of care. The path we followed to conceive of, research, and write this white paper on 21st century medicine can be traced back to 2006, when the Fountainhead Foundation approved a grant to The Institute for Functional Medicine to establish and manage a scholarship program for medical schools and residency programs to send selected faculty, students, and residents to learn about functional medicine. Over a two-year period, 57 scholarships were awarded, representing 27 medical schools and 6 residency programs. The impact and opportunities that have grown out of this seed funding have been significant, immediate, and wide-ranging across academic medicine, clinical programs, fellowships, and residency programs.

Our interviews, meetings, and follow-up discussions with scholarship recipients and their colleagues underscored the fact that IFM needed to provide a rationale and methodology for facilitating a more systematic and widespread introduction of functional medicine into these diverse institutions and programs. It is very arduous to modify both the process and content of medical education. There must be a compelling reason and a clear path toward the goal. Our journey therefore, involved documenting the urgent need for a major shift in medical education, and then describing a model of care that can be adapted to the teaching needs of medical (and other health professions) schools and residency programs. In so doing, we provide both the justification for, and a description of, the change that must occur to equip clinicians to adapt successfully to the health care demands of the 21st century.

We looked first at relevant major themes in health care today: the epidemic of chronic disease; the evolution of evidence-based medicine; the poor performance of the acute-care model in a chronic care environment; the emergence of new paradigms such as systems biology, integrative medicine, and personalized care; and the lack of consensus on how to address these issues in a systematic way. This journey took us deep into the literature of costs vs. performance, science vs. art, research vs. clinical practice, and the many ideas about how to consolidate the gains of the 20th century without losing flexibility or constraining the promise of new information and new models of care for the future.

With this background in place, we began to explore how all of this looks and feels to the individual clinician who is immersed in the daily demands of clinical practice. This, of course, is where the rubber meets the road. We found that not only have we failed to materially assist most primary care practitioners in understanding how to make better use of evidence, or in translating new tools and ideas into their clinical practice, but we have left clinical medicine poorly equipped to address two critical elements: (1) managing the uncertainty that is inherent in clinical practice, and (2) creating a healing partnership with their patients. We found that clinicians are no longer taught how to integrate the science and the art of medicine—indeed, the art of medicine has all but disappeared as a subject of teaching. From the evidence-based medicine perspective, all you really need to do is gather data, focus the data toward securing the diagnosis, and then research the evidence about the best molecule (Rx) or procedure to treat that diagnosis. Doctors trained in the EBM, acute-care model have become technicians. Converging pressures have reinforced this model by forcing doctors to focus their office visits more and more narrowly, and to deliver care in less and less time (often for less and less money).

If this model worked, we wouldn't have had grounds for writing this paper. Unfortunately, the model has failed spectacularly to help stem the rising tide of chronic disease. Fortunately, however, there is plenty of evidence that this is not the only way forward. Physicians and other practitioners *can* be taught to shift into a personalized, systems-medicine approach that is much better adapted to the complex demands of chronic disease. They *can* learn to gather and analyze patient data differently. They *can* twist the kaleidoscope and apply critical thinking to the use of evidence. And they *can* create healing partnerships that allow both patients and practitioners to achieve insight and then to evaluate that insight in the light of knowledge and experience.

Reintegrating the Science and Art of Medicine

There are always two deeply powered processes at work in any life-changing endeavor. Human beings require both denotative and connotative information for mastery—that is, we need both data and intuition, science and art. Brain scientists have made great progress in illuminating the deep creative processes by which our “minds” make use of the “matter” of our brains.”^{1,2,3,4,5,6} Clinicians, particularly, need to bring to the therapeutic encounter the unique qualities of both right- and left-brain function that have been emerging from brain science research. In the last decade, wider use of functional imaging technology has delivered a much clearer picture of coordinated brain function—why and how it occurs. It is now possible to weave together the integrated functionality of the two sides of the brain in a way that can inform our understanding about a comprehensive patient care model that respects and integrates both the science and the art of medicine.

The Institute for Functional Medicine (IFM) has developed a model of comprehensive care and primary prevention for complex, chronic illness that is grounded in both the science (the *Functional Medicine Matrix Model*) and the art (the *healing partnership* in the therapeutic encounter) of clinical medicine. We call this model functional medicine, and we have taught it for many years. It is not a separate discipline or specialty—it is an approach to clinical care that is both comprehensive and patient-centered. It can be taught to and practiced by any health practitioner who has a background in the basic medical sciences and clinical practice, and it can adapt quickly and easily to emerging evidence. It can also provide a common language and shared principles, organizing tools, and analytic process to support and facilitate integrated health care.

Continuing the Journey

We find ourselves at the beginning of the 21st century faced with a healthcare system in disarray on many levels. We must reassemble the disparate pieces of this baffling puzzle into a new and more coherent pattern (a new operating system). ***The intention of this document is to establish the need for a new model of care, and to make conscious, transparent, and usable the functional medicine model and our methods of teaching.*** We will show how this integrated model can better meet the needs of a population afflicted with steadily increasing rates of chronic disease. We believe that these changes will also help physicians establish a more satisfying basis for clinical practice.

The diligent work and thinking of 20th century clinicians and scientists have brought us to this moment with many tools and key concepts, including:

- ⊗ the art and science of clinical medicine
- ⊗ systems biology and personalized, systems medicine
- ⊗ prospective health care
- ⊗ patient-centered health care
- ⊗ the chronic-care model and the chronic-care team
- ⊗ integrative medicine
- ⊗ nutrigenomics, pharmacogenomics, proteomics, metabolomics
- ⊗ evidence-based medicine (EBM)
- ⊗ right and left brain functionality and the healing partnership
- ⊗ the science and practice of creating insight as part of the therapeutic encounter
- ⊗ the process of managing the uncertainty inherent in the clinical encounter

21ST CENTURY MEDICINE:

A New Model for Medical Education and Practice

We will explore all of these topics in the following pages, and we will address the challenge of synthesizing a model of health care for the 21st century that cogently integrates the best components of both established and emerging knowledge and practices. We will describe a model for therapeutic relationships that enhances the emergence of a healing partnership, that engages all parts of the brain, and that strengthens the bodies, minds, and spirits of both physicians and patients as they share the path toward improved health.

Our heartfelt thanks to the Bitzer Family
and the Fountainhead Foundation
for the ongoing support
that has made this project possible.

Foreword

21st Century Medicine: A Gift to Our Patients and Our Students

As we see our healthcare system falling to pieces in front of us, we must ask some key questions. What is wrong with our views of health, disease, and the provision of care? Why does something that costs so much yield so little for so many? How can we best bring the science and art of medicine to our communities for the greatest good?

Framing this discussion are two very different hypotheses:

- 1 *Advances in medical science and technology will solve all of our personal and global health needs.*
- 2 *Natural healing techniques are safer and more effective than drugs and surgery.*

Between these two points of view, both idealistic persuasions but starry eyed, is a reality about the future of medicine. This vision is well articulated in the monograph, “21st Century Medicine: A New Model for Medical Education and Practice,” by David Jones, Laurie Hofmann, and Sheila Quinn.

The field of functional medicine offers educators, clinicians, and researchers a scientifically valid semantic and conceptual bridge between the benefits of hard sciences, clinical medicine, and integrative practices. Evolving sciences such as genomics, pharmacogenomics, and nutrigenomics offer innovative and promising medical treatments. At the same time, the common sense application of prevention, wellness promotion, improved lifestyle, diet, the use of botanicals and nutritional supplements, mind-body therapies, and other complementary and integrative approaches can be blended with these sciences through the Functional Medicine Matrix Model approach.

This synergy can not only improve our health as individuals and communities, but can close the maw of the gluttonous economic pit that excessive application of medical technology with its “Fix me; I’m broken” paradigm provides to us. Indeed, much of the resistance to changing medicine to a more integrative approach has been rooted in the absence of a common language encompassing what doctors learn to speak during medical school, or in other types of healthcare training programs, and the varied landscapes of complementary and integrative theories and practices.

This new model, as discussed in the monograph, offers cutting-edge systems biology, synthesized with whole-person medicine. This is the best of both worlds. No longer is the patient seen purely through the lens of a dysfunctional organ system, a disease, or a syndrome. By evaluating a matrix of root causes in the diagnostic and therapeutic process, we open our eyes to a different altitude as well as latitude of thinking about complex and chronic disease states. We can look further “upstream” to understand the physiology and pathophysiology and not simply treat the end stage manifestations of that altered physiology.

The Institute for Functional Medicine (IFM) is contributing to the development of medical school curricula to introduce this higher level of reasoning and assessment. IFM has supported a number of academic initiatives to expand the view of the patient from linear cause and effect, symptom and diagnosis, to a broader, real-life phenomenological perspective.

Traversing the view of function, health, and disease from the molecular and genomic to the psychosocial, cultural, and behavioral has always been a breathtaking stretch of mind and consciousness. Bringing this into medical training is particularly challenging even though it offers the opportunity to both respect our students as persons and adult learners, and to meld their interest in science with their desire to heal. It is a way to create a reciprocal language that provides bridges between learners and their patients as well as with their colleagues. This language, embedded with the various functional medicine constructs, expands our ability to communicate and to contextualize our own and our students’ understanding of the underlying science of medicine with the art of healing.

Since our work involves training medical students and residents for practice, we have given much thought, as have the authors of this monograph, to the future of medicine. To conclude we offer some comments we think mirror the authors’ vision in both spirit and values.

The doctor of the future will be an integrative healer whose practice differs in many ways from that of today’s typical physician. The doctor of the future will provide care that is patient-centered and comprehensive (body, mind, and spirit), care that is both high-tech (using genomic prediction tools, systems biology, and functional medicine, for example) and high-touch. Care will focus more extensively on preventing disease and injury. The practice of the future will be provided by smoothly working teams that will include primary care physicians, complementary and alternative health practitioners, health coaches, and wellness mentors, as well as medical specialists, allied health and nursing practitioners. Putting the patient in the driver’s seat allows representatives from any number of disciplines to serve as navigator through the healthcare system, helping people sort through conflicting data as well as the many difficult choices they must make during their lives in times of both wellness and illness. Tomorrow’s physicians will consistently assess new evidence, to ensure that their practices meet the highest standards of quality and patient outcomes.

To a great degree, the body has the capacity to heal itself; this concept, in some ways, opposes the mechanical model in which doctors act as fixers. One goal of future practitioners will be to guide and empower patients toward self-healing. Consonant with this approach will be use of prevention and health promotion, the full range of natural treatments, use of the safest and least expensive interventions first, and also the mobilizing of community and social support for healthy living. This vision of the future doctor does not reflect a purely in-the-clinic model. Future clinicians, if they are to be integrative healers, need to be out where people are and to participate in social and environmental policy change.

As both medicine and medical education evolve in this century, as health care and healthcare reform take shape, we believe that the concepts developed in this monograph will lead the way in thinking and practical application. Integrative Medicine is defined as *the practice of medicine that reaffirms the importance of the relationship between practitioner and patient, focuses on the whole person, is informed by evidence, and makes use of all appropriate therapeutic approaches, healthcare professionals and disciplines to achieve optimal health and healing*.¹ As such, this model of care partners closely with the approach taken in functional medicine to bring the best of our thinking and practice to the bedside and to the community.

The Functional Medicine Matrix Model, as elucidated in this paper, is an essential architecture for the kind of medicine of the future we see both as imminent and necessary.

Executive Summary

In early 2009, an extraordinary degree of public attention was focused on healthcare reform. In Washington, DC, two hearings were held before the Senate Committee on Health, Education, Labor and Pensions, and the Institute of Medicine of the National Academy of Sciences hosted a *Summit on Integrative Medicine and the Health of the Public*. In New York City, a major conference on Integrative Health Care was held. The January/February 2009 issue of *Health Affairs* was devoted entirely to *The Crisis in Chronic Disease*. Why?

We know with certainty now that rapidly rising rates of complex, chronic disease are creating an unsustainable burden on the national economy in both direct (e.g., treatment) and indirect (e.g., lost productivity) costs.⁷ The \$1.3 trillion estimated to be the cost of chronic disease today may well grow to \$4.2 trillion within 15 years.⁸ Health professionals struggle every day to cope with the increase in suffering and disability that accompanies this modern epidemic. At a time when many other urgent pressures on the national economy command our attention, we absolutely **must** sustain our focus on the system-wide changes in health care that will be required in the years ahead if the most severe consequences of this epidemic are to be avoided.

A careful examination of the evidence on both performance and costs in American health care convincingly demonstrates the urgent need for this transformation. We have been taught to believe that we have the best health care in the world, but the facts do not support such an assessment. We spend about twice as much per capita as other industrialized countries and yet we rank shockingly low on most parameters of health.⁹

Many diverse influences are responsible for the current state of the public's health (see Figure 1).^{10, 11, 12} It is not enough, however, to demonstrate, as many experts have done, that the majority of today's chronic diseases could be prevented or ameliorated by changes in lifestyle,¹³ and then suggest that patient responsibility and self-care can take care of the problem. We must also ask what contributes to such unhealthy lifestyles and how can we best equip clinicians to serve the

patients who are living every day under those pressures. It is critical that we understand how great a proportion of environment and lifestyle is influenced by conditions beyond the control of individual patients—not only the genetic vulnerability one is born with, but increases in environmental toxicity, the homogenization and denaturing of the food supply, the influence of sedentary technology on jobs, education, and entertainment, the powerlessness and despair of poverty, the debility produced by chronic stress, and the fragmentation of family and community life that leads to isolation and a lessened sense of purpose and meaning. These are all complex problems that took many decades to create and that will require a long-term national effort and effective leadership in public policy to alter. We recognize—and emphasize—that not only must we change healthcare and medical education (the primary focus of this paper), but over the next decades we must also change the practices and priorities of our political, social, and economic structures to achieve fundamental change in the public's health.

Figure 1: Major Influences Contributing to the Epidemic of Chronic Disease

In order to change our future, however, we must thoroughly understand our past. Therefore, after presenting an overview of the paper (Chapter 1), we focus first on exploring the dominant influences that have helped to shape the current crisis in health care (Chapter 2). Next, we present and discuss the most prominent models that have been proposed for the future (Chapter 3). The implications of these issues

for the practicing clinician are then analyzed (Chapter 4). And last, a preferred model for 21st century medicine is presented (Chapter 5). It is important to recognize that even if patients do everything it is possible for individuals to do for their own health (an idealized state that is highly unlikely to be realized), we still have tens of millions of people with multiple chronic diseases, and well over 100 million with at least one,¹⁴ and both figures are on the upswing. All of these people need more effective therapeutic services, and **everyone** needs more effective disease prevention and wellness promotion strategies in order to cope with the pervasive environmental influences that make achieving health such a challenge.

The transformation of 21st century medicine from the prevailing acute-care model to a far more effective chronic-disease model will succeed only if we attack the underlying drivers of the epidemic—the complex, lifelong interactions among lifestyle, environment, and genetics—and if we engage the entire healthcare system in a concerted effort to implement a unified, flexible approach that can readily adapt to shifting needs and emerging evidence. The central purpose of this paper is to demonstrate that such changes are urgently needed and achievable.

In order to accomplish such an ambitious goal, several key objectives must be achieved. As discussed in the succeeding pages, these include:

1. A shared understanding of the powerful, primary influence of lifestyle and environment upon genetic vulnerability in the initiation and progression of chronic disease must be matched with a therapeutic tool kit that reverses the trajectory toward disease and disability, promotes health, and empowers patients as full partners in the lifelong pursuit of wellness.
2. A more balanced perspective on the appropriate uses of both evidence and insight must be integrated with broad-based clinical skills to establish the foundation for healing partnerships between practitioners and patients.
3. A common set of principles, concepts, and practices that can be used by all health professionals must be taught and applied in clinical practice so that well-trained integrated healthcare teams can be deployed appropriately.
4. A model that incorporates all these elements must pervade education, clinical practice, and research in both private and public arenas.

In this paper, we propose that functional medicine exemplifies the systems-oriented, personalized medicine that is needed to transform clinical practice, education, and research. The functional medicine model of comprehensive care and primary prevention for complex, chronic illnesses is grounded in both science (the *Functional Medicine Matrix Model*; evidence about common underlying mechanisms and pathways of disease; evidence about effective approaches to the environmental and lifestyle sources of disease) and art (the *healing partnership* and the search for insight in the therapeutic encounter). Many years of developing, writing about, and teaching this model to thousands of clinicians in both private practice and academic medicine have demonstrated that functional medicine can enable us to reshape health care for the demands of the 21st century. Using this approach, a healing partnership between doctor and patient can flourish, new and useful insights can be achieved, and a broad array of assessment and therapeutic tools can be utilized by integrated healthcare teams.

Chapter 1

INTRODUCTION

Opportunity

If done right, the development of a health care system that focuses on personalized health planning will be every bit as transformational as the coupling of science to medicine was in the early 20th century.

—RALPH SNYDERMAN, MD, AND R. SANDERS WILLIAMS, MD¹⁵

Throughout the medical system, the heartbeat of impending change has been heard with increasing intensity since the turn of the century. Concepts such as prospective health care, personalized medicine, systems biology, nutritional genomics, integrative medicine, the chronic-care model, and others represent diverse aspects of the impetus to devise a substantively different way of approaching health care in the 21st century. The shift in prevalence from acute to chronic disease^{16, 17} and a growing recognition of the inherent limitations and consequences of shaping medicine primarily around an acute-care model¹⁸ are among the most powerful forces that are driving change. The context of uncertainty that pervades the realm of clinical care¹⁹ demands a comprehensive and flexible model that can integrate evidence relevant to the individual without forcing physicians and other practitioners to manage complex, chronic disease using an acute-care model that is ill-suited to the task. Transformation is imminent—the opportunity is now.

The “next next transformation” will change the paradigm to focus on health—positively defined and measured as something other than the “absence of disease”; conceived as an integrated function of biology, environment, and behavior; and measured as a product of physical, mental, social, and spiritual variables.

—MICHAEL JOHNS, MD, AND KENNETH BRIGHAM, MD²⁰

As we come to the close of the first decade of the 21st century, the opportunity to influence the strategic decisions that will redirect medical education and practice for the foreseeable future will encounter many challenges. Philosophies of health and disease, exciting new models of delivery and management of care, practitioner diversity and interrelationships, emerging perspectives on science

and evidence, and the teaching of analytical thinking and clinical reasoning are all under pressure to evolve. Resistance to change and eagerness for it exist simultaneously within all established systems; both perspectives represent important issues that must be addressed successfully to ensure that changes are purposeful, practical, and effective. Educational programs and leaders will be called upon to set the pace of change, identify the best models, integrate those models into existing curriculums, and advocate for widespread adoption.

We can facilitate this process by taking into account the substantial common ground that already exists among many of the leading innovative paradigms, even when they are not directly comparable in intent or in practical applications. Congruent elements can be identified, extracted, and synthesized to inform a comprehensive new model that will be compatible with both established and emerging approaches to health education and practice. In addition, there are important principles and practices that can provide a solid foundation for synthesizing these congruent elements into a workable new model.

Visualizing and implementing a fresh approach to health and disease will require collaborative efforts and systems that work to the benefit of patients and practitioners alike. In this paper, we will describe how certain key forces and concepts are critical components of a dedicated effort to achieve productive and lasting improvements in our healthcare system. We will demonstrate how the common themes in these overlapping paradigms represent fertile terrain for synthesizing a comprehensive new model. We will identify elements that must be added to the common themes to create an effective model for teaching and practice. And we will describe that new model and advance suggestions about how to strengthen and implement it. The ideas are (metaphorically) bursting out of the literature, essential tools are being developed, and the pivotal technologies are rapidly advancing—the moment is ripe with promise.

Purpose

Our overarching purpose in writing this paper is to illuminate a path toward health and vitality for patients—not an easy or straightforward task in a world of increasing complexity and epidemic levels of chronic disease (Chapter 2). ***The intention of this document is to establish the need for a new model of care and to make conscious, transparent, and usable the functional medicine model.*** We offer to academic medicine leaders, practicing physicians, and other health professionals a model that we believe will substantially improve management of disease risk and assessment—as well as treatment for the millions of patients who already suffer from complex, chronic disease—using personalized, systems-oriented, cost-effective approaches. Blending the foundational principles and practices of functional medicine with the substantial common ground that already exists in emerging models clarifies a more comprehensive and effective model of teaching and practice for medical schools, residency programs, and eventually other health professions schools. Such an ambitious goal will succeed only if the plans rest upon a solid foundation that resonates strongly with leaders and early adopters in medical education and the health professions. Strategic objectives and effective tools to guide action steps appropriately will be required. The need for change and the matching of solutions to problems must be clear and persuasive. This paper will analyze emerging trends and needs and address the power of this synthesized model to shape those trends and meet critical needs in order to help improve the education and effectiveness of healthcare practitioners and offer their patients a better path toward lifelong health.

Emerging Models

From among the creative and fascinating new paradigms, we will address six that have emerged as leaders and already claim many adherents. They share a great deal of common ground that is critical to a synthesized, comprehensive model for 21st century medicine. Each of these new models, while incomplete in itself, contains elements that help to ensure compatibility and integration into an overarching approach. These will be discussed in much greater detail in Chapter 3, but here we introduce the key concepts of each model. (There are other models of note, of course, including the Future of Family Medicine project and the Medical Home project; information on both of these is provided in the Appendix. In the body of this paper, however, we have narrowed our discussion to the models that appear to have the greatest potential impact on the actual content of care, rather than the structure of care.)

A graphic representation of some of the common themes and key concepts in these six models can be seen in Figure 2.

Figure 2: Common Themes and Key Concepts Among Emerging Models in Medical Education and Clinical Practice

1. Personalized medicine

Personalized medicine is often rather narrowly defined to comprise primarily the development of genetic tests to identify risk factors for adverse or unpredictable drug effects and to identify individuals who are most appropriate for certain kinds of drug therapies or diagnostic procedures.^{21, 22} This kind of assessment should certainly help to improve the matching of drugs and diagnostics to individual patients and, as a result, may also help to reduce death, disability, and costs associated with individual differences in the biotransformation of drugs and other substances.²³ However, under the rubric of personalized medicine lie many other complex issues relevant to biochemical, physiological, genetic, and environmental individuality that must also be attended to if we hope to reverse the modern epidemic of chronic disease and assist patients toward healthier lives. This broader model of personalized care has already become an explicit component of systems biology and prospective health care, and it is implicit in the chronic-care model and integrative medicine as well. Personalized medicine is critical to the future of health care.

2. Prospective health care

A bold new model for 21st century medicine called prospective health care was proposed in 2003 by Snyderman and Williams.²⁴ Pilot projects have been initiated and are being tested now at Duke University. In a 2006 article,²⁵ Snyderman and Langheier described their rationale in terms completely consistent with the focus of functional medicine for the past two decades:

Chronic diseases develop as a consequence of an individual's baseline susceptibility coupled with their exposure to environmental factors. These may trigger initiating events, leading to the accumulation of pathological changes and the onset and progression of chronic disease. Today, most health-care expenditure is focused on the later stages of this process, long after the development of many underlying pathological changes. Until recently, it could be argued that the focus on treating disease was justified because the ability to predict, track, and prevent its onset was not technically feasible. This is no longer the case, and the emerging sciences of genomics, proteomics, metabolomics, medical technologies and informatics are revolutionizing the capability to predict events and enable intervention before damage occurs. Personalized risk prediction and strategic health-care planning will facilitate a new form of care, which we have called "prospective health care."

Including the same four elements as systems biology (prediction, prevention, personalization, and participation), prospective health care offers a much broader perspective, describing structural and procedural transformations that must also occur in reimbursement, research, risk management assessment, record keeping, and the delivery of care.²⁶ The thrust of these changes is "toward managing disease risk and providing personalized care for chronic and acute disease."²⁷

3. Chronic-care model

The full chronic-care model (CCM), first conceived in 1993, was formally presented in a 2001 publication by Wagner et al.²⁸ Since that time, it has undergone serious study, implementation, and revision to accommodate experiences in clinical settings and findings from research. Emerging evidence has shown fairly conclusively that patient outcomes in a variety of chronic conditions can be improved whenever substantive progress is made on integrating the elements of this model into clinical practice. Core elements include:

- ⊗ Productive interactions between informed, activated patients and prepared practice teams
- ⊗ Effective patient self-management strategies
- ⊗ Delivery system redesign (team approach; multidisciplinary, planned interventions instead of acute, reactive interventions; use of case managers; regular follow-up)
- ⊗ Decision support (integration of evidence-based guidelines into the flow of clinical practice so that information to support clinical decision making is readily available)
- ⊗ Clinical information system (the use of a database and other resources that bring timely, relevant information to both physicians and patients)
- ⊗ Community resources and policies

CCM has in common with prospective health care a strong emphasis on redesigning the systems that support and shape clinical practice. Both have explicit emphases on a team approach to chronic care, the necessity of patient self-management, and the urgent need to involve community resources and attract the attention of policymakers.

4. Evidence-based medicine

Evidence-based medicine (EBM) is “the conscientious, explicit, and judicious use of current best evidence in making decisions about the care of individual patients. The practice of EBM means integrating individual clinical expertise with the best available external clinical evidence from systematic research.”ⁱ

We include EBM in the analysis of emerging models because of its growing influence on clinical practice and medical education. Although it is not, in and of itself, a type of medical education or clinical practice, at its best it can provide practitioners and healthcare delivery organizations with more current and focused decision support through the integration of relevant research findings into clinical decision making. Although EBM is intended to reduce uncertainty and improve the consistent use of best practices in patient care, experimental designs have not yet caught up with the complexity of chronic disease, the multiple needs and diverse presentations of patients in the clinical setting, and the multifactorial interventions that are required to address such diversity and

ⁱUsed with permission of the Centre for Evidence-based Medicine. A more expanded definition of Evidence-based medicine is included in the Appendix.

complexity.²⁹ EBM cannot replace analytical thinking, clinical reasoning, and clinical experience,³⁰ although sometimes it is presented as doing just that. Improperly applied, EBM can place patients in serious jeopardy.³¹ Ideally, it can be used to increase practitioner effectiveness if its strengths are appropriately utilized and its limitations are clear: “The methods of EBM do not supply ‘correct’ answers but rather information that can improve clinical judgment.”³² Ultimately, the appropriate use of EBM relies on a more precise definition of what constitutes relevance and best evidence for each individual patient encounter.

5. Systems biology

The Institute for Systems Biology in Seattle, Washington, identifies four factors that comprise its field: prediction, prevention, personalization, and participation. Although elsewhere systems biology is not defined quite so broadly, it is useful to consider it through this wide-angle lens, for it makes readily apparent the interconnections with integrative medicine, prospective health care, and personalized medicine that open the door to a synthesized model. Systems biology as currently pursued focuses primarily, as does personalized medicine, on genetic mechanisms in drug responses, but given a broad vision—and the will and funding to execute on that vision—it could become the scientific engine driving clinical medicine toward the model we are proposing. A more detailed description from the Institute for Systems Biology’s Web site is provided in the Appendix.

6. Integrative medicine

In the years since 1999, when eight academic medical institutions first met to discuss the emerging field of integrative medicine, active participation among academic medical centers has grown dramatically. Now more than 45 institutions are members of the Consortium of Academic Health Centers for Integrative Medicine (CAHCIM), comprising many of the finest medical schools in the country, with several having endowed centers or foundations to support expanded development in the field. Their collective mission is:

...to help transform medicine and health care through rigorous scientific studies, new models of clinical care, and innovative educational programs that integrate biomedicine, the complexity of human beings, the intrinsic nature of healing and the rich diversity of therapeutic systems.³³

Their definition of integrative medicine is:

...the practice of medicine that reaffirms the importance of the relationship between practitioner and patient, focuses on the whole person, is informed by evidence, and makes use of all appropriate therapeutic approaches, healthcare professionals and disciplines to achieve optimal health and healing.

³³See list of CAHCIM members in the Appendix.

Several elements of integrative medicine are highly relevant to the model proposed in this paper:

- ⊕ The openness to new diagnostic and therapeutic strategies (e.g., nutrients, botanicals, mind-body interventions, acupuncture) and to cooperation with health professionals from other disciplines signals an important readiness to develop a fully integrated healthcare model—one in which the patient is the central focus and all practitioners have in common certain critical elements of language, philosophy, and clinical practice.
- ⊕ The commitment to adopt innovative approaches in education is essential to the transformation of medicine.
- ⊕ The emphasis on the value of practitioner-patient relationships and the focus on the whole person will play a significant role in the medicine of the future. These values—formerly so intrinsic a part of medicine that they went almost unnoticed—are receiving renewed attention now that their disappearance from much of medical care has become apparent. They are absolutely vital components of a transformed approach to health care.

Summary

In this white paper, we will establish the need for a new model of education and care; we will address forces that may represent obstacles to change; and we will explore the key concepts and elements already present in science and medicine that are ripe for synthesis into a new, more comprehensive model. Our goal is to make improvement in medical education programs and clinical practice *feasible*—not in an abstract or ideal sense, but in the real world with all its resistance to change and discomfort with emerging concepts. To that end, funding has already been secured for the development of a pilot project for adapting the model to medical education. Before being finalized, each phase of the project will be reviewed by a small group of leaders within academic medicine who are interested in achieving a major shift in medical education, so that we tailor our recommendations to the audience with as close a fit as possible. IFM is pleased to announce that the roll-out of the first academic medicine project is scheduled for the first half of 2011. Our aim is nothing short of inspiring system-wide change—the transformation of medicine is imminent, it is urgently needed, and it is entirely possible.

Chapter 2

THE CHANGING MEDICAL ENVIRONMENT

Background

There are, literally, innumerable facts and statistics available with which to describe and analyze health and health care. Any discussion must of necessity be based on a selected subset of the data and, thus, subject to the bias of the authors. We have, for example, omitted such critical issues as the reimbursement structure, governmental regulatory influences, health disparities, environmental degradation, and the uses of technology—all topics on which reams of important material have been written. Our goal here is not to cover everything that is either problematic or of value within the medical environment, but to concentrate our thinking on well-established data that help to illuminate an overarching problem—that we are losing the battle against chronic disease and that fundamental change will be required to improve our performance.

Global and economic issues

The healthcare system is influenced by increasingly complex and varied issues. Although many of these are beyond the scope of this paper, we would be remiss if we did not at least acknowledge their importance:

- ✦ The growing ethnic diversity of the U.S. population poses challenges of communication, varied beliefs and preferences about treatment, and the adverse impact of the standard American diet (SAD) on genetically vulnerable populations. [An excellent overview of emerging global health issues that are brought to the U.S. by immigrant populations can be found in the July/August 2008 issue of *Health Affairs*, which focuses on India and China. These articles demonstrate unequivocally that health issues in the developing countries parallel those of the developed world, as affluence, sedentary lives, and fragmentation of communities increase while food quality and diversity decrease.]

- ⊕ The transmissibility of new diseases (e.g., avian flu) between species and across the world's continents poses a special challenge to both acute and chronic care.³⁴
- ⊕ Economic shifts that are strongly affected by global markets could have profound effects on the U.S. model of healthcare financing, an issue that has been under considerable scrutiny for many years already. Increasingly, the evidence identifies our patchwork approach to reimbursement as a considerable barrier to equitable and effective care.³⁵
- ⊕ Importation and transportation of foods, prescription drugs, botanicals, and nutraceuticals among countries with widely differing quality control and environmental standards will affect virtually every citizen over time.

While we focus in this paper on models for clinical practice and medical education, we should keep the above issues in mind, because they will continue to influence both the healthcare system and individual health.

The pharmaceutical and acute-care models

The acute-care model is characterized by rapid differential diagnosis aimed at prescribing a drug (or procedure) that will ameliorate the patient's presenting symptoms and avert the immediate threat.³⁶ It minimizes the involvement of the patient, who functions as a mostly passive recipient of the procedure or prescription.³⁷ It is not a model that reimburses the practitioner for looking into why the patient became ill, or whether she/he will be back many times for ramifications of the same underlying problem.³⁸ Instead, it prioritizes quick solutions to the most pressing problems. It is, of course, absolutely essential in emergency and hospital-based care, but difficulties arise when this model is applied to ongoing, community-based care, a process that accelerated under the managed-care movement (which turned

Figure 3:
Forces Narrowing the Focus of 20th Century Medicine

out to be far more about managing costs than managing care) and the direct-to-patient advertising of drugs. With hindsight, it seems as though everything has been pushing the system toward this narrowed focus, regardless of fit (Figure 3).

The advances achieved by drugs in curing acute infections and managing some of the most threatening diseases mankind has faced were dramatic in the last century. The extended romance with pharmaceutical medicine, which first blossomed in the early 1930s when penicillin began to cure previously intractable infectious diseases, has now dominated medicine and medical education for more than seven decades. From depression to diabetes, from heart disease to asthma, the search for therapeutic compounds that can be patented as drugs continues unabated. The accompanying financial incentives have attracted (and perhaps distracted, see **Sidebar**) some of the best minds and most influential leaders in research and medical education, including those engaged in the development of systems biology and personalized medicine, both of which are primarily focused on pharmacogenomics at this time (see Chapter 3 and the Appendix for more information on these models).

Costs and Performance in the Battle for Health

It is discouraging to note that among the vast array of peer-reviewed medical research reports published every year, there is so little that addresses whether the overall health of the population shows an adequate positive response to current medical treatment. Thousands upon thousands of studies compare one drug to another without ever acknowledging that Americans are far less healthy—at far greater cost—than their counterparts in the rest of the industrialized world. The reduction in deaths from, for example, heart disease is emphasized,⁴⁵ while the fact that we have failed to prevent CVD—even while reducing, through drugs, the prevalence of CVD risk factors such as hypertension and high cholesterol⁴⁶—is too often ignored. In fact, we must turn primarily to philanthropic or governmental agencies for data and analyses that reveal the scope of the failure. “The Milken Institute recently estimated that the most common chronic diseases cost the economy more than \$1 trillion annually, mostly from lost

Research Bias: The Pharmaceutical Hegemony in Funding and Focus

Opportunities lost are perhaps the greatest concern in the dominance of the pharmaceutical research model. Too often, the search for drugs that will pay off for investors and executives of pharmaceutical companies determines the research agenda. Rather than being driven by patient needs, public health priorities, or scientific curiosity about mechanisms and pathways, the profit motive is the driver of the research agenda,³⁹ and the gains to science and health are collateral outcomes, not central purposes. Lest we think this is trivial, consider that 70% of the money for clinical drug trials in the U.S. comes from the pharmaceutical industry.⁴⁰

“Scientifically, a neutral or negative trial is as valuable as a positive one, although commercially this is clearly not the case.”⁴¹ Unless all results are available to the scientific community, the evidence record about those drugs that are investigated can be significantly skewed by the absence of negative or neutral findings. The value to academic researchers (and their institutions) of bringing in large clinical trials with drug company funding may be very significant; promotions, recognition, and supplemental income provide a triple-threat incentive that is virtually impossible to ignore when considering research priorities.^{42, 43}

Many studies have shown a bias toward positive results when the research was funded by the drugs’ manufacturers.⁴⁴

worker productivity, which could balloon to nearly \$6 trillion by the middle of the century.”⁴⁷ If nothing else, that estimate alone should galvanize us to action!

The broad education in science and clinical arts that physicians experience today is expressed in clinical practice through a constricting and linear process that is primarily aimed at naming a drug of choice for the patient at hand.⁴⁸ Unfortunately, 50 years of such practices have failed to stem the rising tide of chronic diseases among both young and old,⁴⁹ while related problems have emerged to cause great concern:

- ⊗ The **cost of care** is unmanageably high and rising,⁵⁰ driven by the high costs of hospitalization⁵¹ and drugs,^{52, 53} but also fueled by increasing prevalence of complex, chronic disease at all ages of the population.^{54, 55} It is estimated, for example, that more than half of all Americans suffer from one or more chronic diseases,⁵⁶ and that the 8 million Medicare beneficiaries who have five or more chronic conditions accounted for over two-thirds of the program’s \$302 billion in spending in 2004.⁵⁷

The Milken Institute report, *An Unhealthy America* (October 2007), provides the following food for thought:

To quantify the potential savings from healthier lifestyles and plausible but modest advances in treatment, we compared a “business-as-usual” baseline scenario with an optimistic scenario that assumes reasonable improvements in health-related behavior and treatment. The major changes contemplated here are weight control combined with improved nutrition, exercise, further reductions in smoking, more aggressive early disease detection, slightly faster adoption of improved therapies, and less-invasive treatments....

Across the seven diseases, the optimistic scenario would cut treatment (direct) costs in 2023 by \$217 billion.... And the cumulative avoidable treatment costs from now through 2023 would total a whopping \$1.6 trillion. Note that this would be a gift that keeps on giving, saving hundreds of billions annually in the years beyond 2023.

All told, our analysis implies that modest reductions in avoidable factors—unhealthy behavior, environmental risks, and the failure to make modest gains in early detection and innovative treatment—will lead to 40 million fewer cases of illness and a gain of over \$1 trillion annually in labor supply and efficiency by 2023. Compared to the costs we project under the business-as-usual scenario, this represents a 27 percent reduction in total economic impact.

- ⊗ Table 1 displays the **bookends of health: rankings on infant mortality and life expectancy**. The U.S. makes a very poor showing on both, particularly for a country whose citizens have been taught to believe they have the best health care in the world. The U.S. spends twice the median per-capita costs calculated by the Organization for Economic Cooperation and Development (OECD),⁵⁸ has extraordinarily poor outcomes for such a massive investment,⁵⁹ and does not even provide coverage for all its citizens (an estimated 47 million currently uninsured⁶⁰; 75 million under- and uninsured combined⁶¹).

Table 1. Infant Mortality and Life Expectancy Rankings of the United States

Ranking	Country	Infant Mortality ¹	Country	Life Expectancy ²	Ranking
1	Sweden	2.8	Japan	81.4	1
2	Japan	3.2	Switzerland	80.6	2
3	Finland	3.5	Sweden	80.6	3/4
4	Norway	3.6	Australia	80.6	3/4

- ⊗ The **“quick fix” mentality** that drug dependence has fostered in patients creates an unhealthy cycle that drives further drug dependence. Sensible and distinguished voices calling for major long-term investments in helping people establish healthy behaviors and in ensuring a healthy planet have heretofore been mostly ignored in the struggle for attention and funding. And yet, with only a few exceptions, the development of chronic disease is predominantly influenced by multiple interactions between genes and environment experienced over many years; neither factor alone is enough—the genes must be plunged into an adverse environment to express disease and they must be rescued from such environments to restore health (not just suppress symptoms):
- **Walter Willett:** “For most diseases contributing importantly to mortality in Western populations, epidemiologists have long known that nongenetic factors have high attributable risks, often at least 80 or 90%, even when the specific etiologic factors are not clear.”⁶²

- **Kenneth Thorpe:** “Health behavior such as overconsumption of food, lack of exercise, smoking, and stress accounts for 40% to 50% of morbidity and mortality.”⁶³
- **Robert Heaney:** “Discerning the full role of nutrition in long-latency, multifactorial disorders is probably the principal challenge facing nutritional science today. The first component of this challenge is to recognize that inadequate intakes of specific nutrients may produce more than one disease, may produce diseases by more than one mechanism, and may require several years for the consequent morbidity to be sufficiently evident to be clinically recognizable as ‘disease.’”⁶⁴
- ⊗ Drug-resistance phenomena,⁶⁵ **adverse drug reactions**,⁶⁶ and adverse interactions between drugs and foods,⁶⁷ drugs and botanicals,⁶⁸ and drugs and other drugs⁶⁹ now affect millions of lives each year and are a cause of death in unprecedented numbers.⁷⁰ Rates of visits to provide care for adverse drug reactions increased by one-third between 2001 and 2004.⁷¹

On a deeper level, the drug paradigm—and the most rigid part of the evidence-based movement that supports it—may adversely affect clinical judgment. To minimize time spent with patients, physicians are forced to focus on prescribing the “right” drug. Very often, however, the evidence about the “right” drug rests on studies that do not reflect a real patient population as seen in clinical practice⁷²; multiple comorbidities, for example, are usually excluded from RCTs.^{73, 74} Until very recently, nearly all clinical trials failed to account for variations in individual biochemistry and physiology, as well.^{75, 76}

This shift toward rapid prescribing results in a de-emphasis on establishing therapeutic relationships and exploring the patient’s story. Time pressures applied by reimbursement entities make it very difficult to do the analytical thinking that develops broad pattern-recognition abilities. Immensely valuable clinical skills for managing complex, chronic disease and multiple comorbidities are thus being sidelined; as that happens, fears about innovation and creativity surface, a retreat to dogma and linearity becomes apparent, and the idea that the job of medicine is to find the right drug(s) for the most parsimonious diagnosis preoccupies mainstream thought. Such forces separate the physician from many analytical and inferential skills that are likely to be extremely useful in the search for common underlying pathways of chronic disease and for new approaches designed to intervene where such disease actually originates—in the patient’s unique mix of biochemistry, genetics, and environment.

The focus on drugs could be considered both cause and effect of the dominance of the acute-care model that has come to characterize medicine today. As the challenges of infectious disease and trauma gave ground to advances in drugs and surgery, startling successes strengthened the belief that modern medicine would eventually conquer most diseases with those tools, a perspective that only intensified as the profits to be made from drugs and surgery became a magnet for both individuals and institutions. Few scientists or physicians in the 1950s and 60s foresaw a moment when the challenge of chronic disease would swamp the healthcare system and prove resistant to the miracles of 20th century medicine.

Now, however, in the 21st century, we are fully aware that *complex, lifelong interactions between our genes and environmental degradation,*⁷⁷ *unhealthy diets*⁷⁸ (fueled by changes in both eating habits and food supply⁷⁹), *stress,*^{80, 81, 82} *sedentary lives,*⁸³ and *social fragmentation of families and communities*⁸⁴ have surged to the forefront as interwoven causes of chronic disease that are not amenable to treatment with an acute-care model. (Figure 4 depicts the pressures that are forcing a broader process of clinical thinking and care.) With an aging population, these effects are present through many more years of life and thus become impressive cost drivers (see, for example, the Medicare data in Figure 5). The system must expand to address these interconnected trends. Broad-based pattern-recognition and communications skills will be needed to prevent, treat, and reverse the declining function associated with these pervasive influences. We must transform our system of health care through new models for medical education, acute and chronic disease management, research, health insurance, and fiscal responsibility.

Figure 4:
Forces Expanding the Focus of 21st Century Medicine

Figure 5:
Medicare Spending as a Function of Number of Chronic Conditions

Data from Chronic Conditions: Making the Case for Ongoing Care. Johns Hopkins University and The Robert Wood Johnson Foundation: Partnership for Solutions, September 2004.

The seemingly intractable poor performance of American medicine on a wide range of health measures^{85, 86} forces us to pose some critical questions:

- ❖ Does the investment in a paradigm that identifies drugs as the treatment of choice across a broad array of diagnoses still produce the same returns on investment that were achieved in earlier decades?
- ❖ Is a system that seeks to reduce doctor-patient face time to the fewest possible minutes, and that measures effectiveness by how little time and money are spent, going to enable us to address population-wide health needs in the century ahead?
- ❖ Does the acute-care model respond appropriately to the needs of patients already suffering from complex, chronic disease and multiple comorbidities, as well as to the exigency of preventing those diseases for currently healthy people and future generations?

We suggest that not only is the evidence persuasive that the answer to those questions is “no,” but that the continued almost exclusive reliance on pharmaceutical answers to an epidemic of complex, chronic disease may constitute an unintended rejection of some practices critical to improving our response to today’s urgent problems.

Changing Patterns: From Acute to Chronic Disease

The changes in mortality and morbidity in the United States over the last century have been described as a shift from an age of “pestilence and famine” to an age of “degenerative and man-made diseases.”⁸⁷ In other words, infections and undernutrition as relatively straightforward causes of illness and (often early) death have been overwhelmingly superseded by chronic, degenerative conditions caused by multiple, complex influences. In addition to the discovery and development of antibiotics, the great achievements of the public health system⁸⁸—vaccinations; safety in municipal water and sewage systems, foods, medicine, workplace, highways and motor vehicles; prenatal and pediatric care; reduction in smoking—were among the most critical factors in making this shift, particularly in the first half of the 20th century.

Medicine’s focus on the development of a sophisticated and multifaceted pharmaceutical war chest to cope with infectious disease achieved many notable successes. Unfortunately, infectious disease still has an uncomfortable persistence—a way of breaking out in a different guise just when it was thought to be under control—witness the emergence of AIDS, the ability of bacteria and viruses to become resistant to drug treatments, and the ever-evolving influenza virus, to name a few examples. There is no question, however, that pneumonia, influenza, tuberculosis, and diarrhea/enteritis (the leading causes of death in the United States in the early 1900s) have been replaced by heart disease, cancer, and cerebrovascular disease at the top of the mortality list.⁸⁹

The tremendous advantage of this shift is that we can live much longer with chronic than acute diseases.ⁱⁱⁱ Cardiovascular disease (CVD), for example, is the biggest killer,^{iv} even though three of its four primary risk factors (hypertension, hypercholesterolemia, smoking) have been significantly reduced.⁹⁰ Unfortunately, the fourth, diabetes, has increased.⁹¹ Pharmaceutical and surgical interventions have evolved to address both secondary prevention and symptom management. The upshot of this massive, long-term effort is that people with CVD are living longer and the incidence of death from this disease has substantially decreased.⁹²

We could stop there and declare victory, but that would be tragically shortsighted. Although we have reduced the mortality associated with many serious chronic diseases, the prevalence of, for example, cancer, diabetes, asthma, and heart disease—and the conditions that precede and perpetuate them—has grown, rather than diminished. Rising disease prevalence is complex, of course, composed of at least three primary factors: “...a rise in the population prevalence of disease, changes in clinical thresholds (and awareness) for treating and diagnosing disease, and new technologies that allow physicians to treat additional patients with a particular medical condition. A rise in total disease prevalence (both diagnosed and undiagnosed) is associated with changing population risk factors such as obesity. For instance, among adults ages 20–74, obesity prevalence increased from 14.5% (1976–1980) to 30.4% 20 years later (1999–2000). During the same period, total diabetes prevalence, which is clinically linked to obesity, increased 53%, and diagnosed (treated) diabetes prevalence increased 43%.”⁹³

ⁱⁱⁱ In the last century, overall life expectancy has risen from 51 to 79.4 years for women and from 48 to 73.9 years for men. Source: Chapter on Human Health, EPA Report on the Environment, 2003. Available at <http://www.epa.gov/roe/roe/html/roeHealthSt.htm>.

^{iv} “According to the NCHS, if all forms of major CVD were eliminated, life expectancy would rise by almost seven years. If all forms of cancer were eliminated, the gain would be three years.” Heart Disease and Stroke Statistics—2008 Update, American Heart Association. Cited source: U.S. Decennial Life Tables for 1989–91, Volume 1, No. 4. Eliminating Certain Causes of Death, 1989–91. NCHS, September 1999.

The Role of Obesity in Chronic Disease

Focusing on the role of obesity in chronic disease could pay untold dividends. “[O]ne of the most heritable of human traits,”⁹⁴ obesity is also profoundly influenced by lifestyle and environment.⁹⁵ It fuels (and can be exacerbated by) chronic diseases with high morbidity as well as mortality—cancer, diabetes (now projected to touch 30-40% of all Americans during their lifetimes), heart disease, and depression. As an outcome of the rise in diabetes and other obesity-driven diseases, Olshansky et al. made the shocking projection in 2005 that “... the steady rise in life expectancy during the past two centuries may soon come to an end.”⁹⁶ In other words, if current trends continue unchecked, future generations will have shorter and less healthy lives than the adults of today.

The urgency of this situation is underscored in many compelling—and poignant—scientific papers that highlight some of the profound effects of the obesity epidemic on all age groups:

- » **Elderly:** “Obese seventy-year-olds will live about as long as those of normal weight but will spend more than \$39,000 more on health care. Moreover, they will enjoy fewer disability-free life years and experience higher rates of diabetes, hypertension, and heart disease.”⁹⁷
- » **Adults:** “Two-thirds of adults in the United States today are obese or overweight.”⁹⁸ “...the prevalence of diagnosed type 2 diabetes mellitus continued to increase concurrently with increases in obesity.”⁹⁹

The current (and growing) dominance of chronic and degenerative diseases in the population is accompanied by many grave problems in addition to shortened life expectancy for today’s children: increasing disability over time, lowered quality of life, and far greater costs—both for direct treatment and as a result of important factors such as lowered productivity, reduced income due to early disability, and the cost of supporting disabled people in society for many years. As discussed above, the cost of simply treating—with all the tools and expertise at our command—the current epidemic of chronic disease threatens to either bankrupt us or to displace resources needed for other urgent priorities such as education, infrastructure, social security, defense, research, and countless other vital activities.

We also know with greater certainty that longer life without vitality and health imposes a considerable burden in addition to the costs of treatment:

- ❶ Depression is strongly associated with chronic disease; it has become one of the world’s most common conditions and results in severely decreased quality of life and increased direct and indirect costs.¹⁰⁵
- ❷ Overall health-related quality of life (HRQOL) has gone down as chronic disease rates have risen. The Mortality and Morbidity Weekly Report Surveillance Summaries reported that “during 1993-2001, the mean number of physically unhealthy days, mentally unhealthy days, overall unhealthy days, and activity limitation days was higher after 1997 than before 1997. ...Adults increasingly rated their health as fair or poor and decreasingly rated it as excellent or very good.”¹⁰⁶
- ❸ Prolonged stress is exerted on families that provide care for disabled elders. “An estimated 16 million Americans—more people than live in all of New England—find themselves ‘sandwiched’ between two generations, struggling to raise their kids while caring for an aging loved one. That number is about to explode: In 25 years, there will be 60 million Americans between the ages of 66 and 84, many of them needing full- or part-time care.”¹⁰⁷

- ⊗ Creativity and innovation are lost to underemployment or unemployment and the shrinking work force must support an increasingly disabled aging population for many more years.

We can and should feel grateful that the threat of acute disease decreased so substantially over the last century and, concomitantly, that our life expectancy increased dramatically. We must also recognize, however, the urgent need to redirect some of our healthcare dollars, energy, expertise, and time toward stopping and ultimately reversing the spread of chronic disease. While it is certainly true that we all must die of something, and conquering acute disease made space for chronic diseases to rise to the top of the mortality charts, we cannot allow our much longer lives to be increasingly haunted by unprecedented rates of chronic disease and its accompanying disability, depression, and sharply rising costs. Instead of spending all our resources on managing symptoms and secondary prevention, we must turn our attention to causal factors. We know with steadily increasing confidence and knowledge that the primary driver of chronic disease is the interaction among genes, activities of daily living (lifestyle), and the environment. Describing a model that folds that very general awareness into actual clinical practice, enabling physicians to acquire effective skills and tools for addressing the unique pattern of each individual patient's life and health, is the ultimate goal of this paper.

- » **Adolescents:** "...extrapolation from current data suggests that adolescent overweight will increase rates of CHD among future young and middle-aged adults, resulting in substantial morbidity and mortality ... more than 100,000 excess cases of CHD attributable to the increased obesity."¹⁰⁰
- » **Children:** Type 2 diabetes, previously almost unheard of in children, "...has become common among the pediatric age population, accounting for ~40% of all diabetes diagnosed."¹⁰¹

A (highly simplified) model of the multiple, complex influences that create obesity and associated chronic diseases:

If we concentrate our resources at the bottom of the diagram, on pharmacogenomics, we have already lost the battle; chronic disease is already entrenched and the costs of treating it will only rise.

The Role of Obesity in Chronic Disease, continued

It is important to note, however, that there is no precise, predictive formula. One person's obesity is not identical in cause, signs and symptoms, or secondary outcomes to another's, and thus both treatment and prevention must be individualized to accommodate the genetics, lifestyle, and environment of each patient. Any model for managing chronic disease that does not address all of these components will fall short in comprehensiveness and effectiveness. In a 2008 publication in *Circulation*,¹⁰² the American Heart Association described a comprehensive population-based approach to preventing obesity, including the following key strategies (among others):

- » Prevention at the population level, with emphasis on key risk subgroups
- » Differentiating environmental and policy approaches from clinically-based interventions
- » Use of an ecological model that “includes multiple layers of influences on eating and physical activity across multiple societal sectors”

Often in medicine the marshaling of substantial and focused resources to fight a public health problem waits upon the research agenda. While there are many questions yet to be answered about how and why obesity develops and how and why it is such a risk factor for other serious diseases, it is a long and expensive process to test and verify strategies for prevention and treatment.¹⁰³ We cannot afford

Improving the Response to Chronic Disease

Chronic disease is now the principal cause of disability and use of health services and consumes 78% of health expenditures. (p. 1057 in the publication cited) [D]eveloping a different way to practice medicine for chronic disease is at the heart of any solution to the problem. (p. 2975, a reply to letters generated by the cited publication)

—HALSTEAD HOLMAN, MD, JAMA, 2004¹⁰⁸

The burden of harm conveyed by the collective impact of all of our health care quality problems is staggering. It requires the urgent attention of all the stakeholders: the health care professions, health care policymakers, consumer advocates and purchasers of care. The challenge is to bring the full potential benefit of effective health care to all Americans while avoiding unneeded and harmful interventions and eliminating preventable complications of care. Meeting this challenge demands a readiness to think in radically new ways about how to deliver health care services and how to assess and improve their quality. Our present efforts resemble a team of engineers trying to break the sound barrier by tinkering with a Model T Ford. We need a new vehicle or perhaps, many new vehicles. The only unacceptable alternative is not to change.

—MARK CHASSIN, MD, MPH; IOM NATIONAL ROUNDTABLE ON HEALTH CARE QUALITY, JAMA, 1998¹⁰⁹

The three arenas in which fundamental change is required in order to improve both prevention and treatment of chronic disease are medical education, clinical care (which is conditioned by medical education), and consumer/patient behavior. This paper focuses primarily on clinical care.

Medical education

The Institute of Medicine report, *Crossing the Quality Chasm*, in the chapter on “Preparing the Workforce” (p. 213) observes: “Despite changes that have been made, the fundamental approach to medical education has not changed since 1910.”¹¹⁰ The report also addresses some of the factors that make changing medical education very difficult. However, it does not directly address the imperative to integrate creative and innovative approaches to chronic disease into the process. Medical education must teach physicians to quickly and skillfully differentiate situations requiring an acute-care intervention from those presenting the very different challenge of complex, chronic disease. Once that

differentiation is achieved, then physicians must be given new tools, information, and skills with which to address the common comorbidities and complexities of chronic disease. Key concepts that underlie and will facilitate these fundamental changes are presented in Chapters 4 and 5 of this paper.

Clinical care

Changes in the roles of both patients and clinicians are critical to transforming our healthcare system. Chapter 4 addresses “The Clinician’s Dilemma”: how to practice in such a way that both the continuing advances of science and the essential art of medicine are integrated seamlessly into clinical practice, neither overshadowing the other. Clinicians must improve their capacity to incorporate important emerging evidence into a personalized, systems-oriented model of care, within the context of a strong healing partnership with patients. Chapter 5 presents the functional medicine model and methods that facilitate this evolution as well as an approach to establishing and strengthening the healing relationship. Two cases that exemplify the process are presented in the chapter, and two more cases, organized in a detailed and comprehensive functional medicine model, are presented at the end of the Appendix.

Consumer (Patient) needs and preferences

The growth and sustained energy of consumer interest in alternative and complementary medicine over the last quarter century is one indicator of the desire patients have for a different kind of healthcare system. Although not addressed directly in this paper, healthcare consumers must be assisted to take a lifelong interest in the forces that push each of us toward health or disease. As difficult as it is for physicians and other health practitioners to alter their mode of practice, that’s how difficult it is for patients to alter their mode of living to maximize the prospects of health and minimize the risks of disease. These changes represent a major undertaking and we will not be successful unless both consumers and providers of health care commit to a long-term, sustained effort.

that delay; there are far too many lives at stake. Dr. Richard Horton, editor-in-chief of *The Lancet*, addressed this issue in an editorial titled, “The Precautionary Principle”:

*We must act on facts, and on the most accurate interpretation of them, using the best scientific information. That does not mean we must sit back until we have 100% evidence about everything. Where the state of the health of the people is at stake, the risks can be so high and the cost of corrective action so great, that prevention is better than cure. We must analyze the possible benefits and cost of action and inaction. Where there are significant risks of damage to the public health, we should be prepared to take action to diminish those risks even when the scientific knowledge is not conclusive, if the balance of likely costs and benefits justifies it.*¹⁰⁴

We must act in concert with emerging research, being willing and able to adapt as new information becomes available. That is why we need a model of care that is comprehensive, yet flexible; science-based but not rigidly bound to an imperfect and incomplete evidence base; personalized and holistic. That model will be presented and discussed in Chapters 4 and 5.

Chapter 3

EMERGING MODELS

Personalized Medicine

*If it were not for the great variability among individuals,
medicine might as well be a science, not an art.*

—SIR WILLIAM OSLER, 1892

What is it?

Personalized medicine can be described as the effort to define and strengthen the art of individualizing health care by integrating the interpretation of patient data (medical history, family history, signs, and symptoms) with emerging “-omic” technologies—nutritional genomics,^v pharmacogenomics,^{vi} proteomics,^{vii} and metabolomics.^{viii,111} Developing these strategies is critical to enabling physicians to match individual patients to the best diet, environment, nutraceuticals, and pharmaceuticals for their genetic make-up—a process that will eventually revolutionize medicine. Such a comprehensive individual fingerprint is still many

^v“**Nutritional genomics or, as commonly used, nutrigenomics:** The study of how different foods may interact with specific genes to increase the risk of common chronic diseases such as type 2 diabetes, obesity, heart disease, stroke and certain cancers. Nutrigenomics also seeks to provide a molecular understanding of how common chemicals in the diet affect health by altering the expression of genes and the structure of an individual’s genome. The premise underlying nutrigenomics is that the influence of diet on health depends on an individual’s genetic makeup. (From MedicineNet.com)

^{vi}“**...pharmacogenomics** includes identifying candidate genes and polymorphisms, correlation of polymorphisms with therapies, prediction of drug response and clinical outcomes, reduction in adverse events, and selection and dosing of drugs based on genotype.” (Issa, 2007)

^{vii}“**Proteomics:** The study of the proteome, the complete set of proteins produced by a species, using the technologies of large-scale protein separation and identification. The term proteomics was coined in 1994 by Marc Wilkins who defined it as “the study of proteins, how they’re modified, when and where they’re expressed, how they’re involved in metabolic pathways and how they interact with one another.” (From MedicineNet.com)

^{viii}“**Metabolomics/Metabonomics:** The study of metabolic responses to drugs, environmental changes and diseases. Metabonomics is an extension of genomics (concerned with DNA) and proteomics (concerned with proteins). Following on the heels of genomics and proteomics, metabolomics may lead to more efficient drug discovery and individualized patient treatment with drugs, among other things. (From MedicineNet.com)

Integrating Pharmacogenomic Testing in Clinical Practice

McKinnon et al.¹¹⁵ describe a general process for developing pharmacogenomics tests that can be used in clinical practice. Each of these steps represents a point at which poor outcomes may completely stall the development of an affordable and effective clinical test:

1. Identify circumstances in which knowledge of inter-individual variation in drug response is likely to improve clinical (or financial) outcomes
2. Find a significant genotype-phenotype association
3. Determine reproducibility across ethnic populations
4. Propose model of how genotyping would guide clinical practice
5. Collect data on cost effectiveness of new pharmacogenomic profile vs. current practice
6. Educate stakeholders on appropriate use
7. Implement testing in a staged manner

years away from being feasible, in research or clinical practice. It is not too early, however, to begin learning about it and applying key concepts and early data to patient care in incremental steps as the evidence base advances.

To date, the research underlying personalized medicine has concentrated mostly on pharmacogenomics. The knowledge that “a relatively large number of patients treated for cancer, infectious disease, psychiatric illnesses, respiratory diseases and cardiovascular conditions are not responding to the drugs they are given”¹¹² has been one of the key drivers of the field. The process of developing new drugs specifically designed for personalized applications involves many phases: identification and screening of candidate genes; detection and description of various polymorphisms that affect drug response (e.g., slow or rapid metabolizers); the correlation of each polymorphism with possible therapeutic targets; and the evaluation of clinical outcomes with large enough study sizes to create confidence in the efficacy of the new strategy. All of these steps must occur before selection of a drug and specification of therapeutic dosage can be based on genotype.¹¹³ Once the drug development process is complete, the transformation of research-based data into a new tool for clinical practice must await a cost-effective screening test for patients (a process that involves many challenging and time-consuming phases—see **Sidebar**), delineation of which patients should be screened and at what stage in their care, and long-term follow-up to check for possible adverse effects of therapy. The identification of drugs already in the pharmacopeia that have inter-individual variability in dosing, efficacy, and/or side effects that would make them amenable to a pharmacogenomics approach will also be a lengthy and expensive process, as there are thousands of drugs that could be tested for such personalized applications. Screening tests to detect various polymorphisms must also be developed and they must be cost effective if they are to be utilized routinely in clinical care. Pharmacodiagnostic tests that enable clinicians to quickly and cost effectively identify patients who are at risk for adverse drug responses “must possess high sensitivity and specificity with regards to their predictive performance.”¹¹⁴

A couple of examples will indicate the incalculable potential—and the complexity and costliness—of pharmacogenomics as a clinical strategy:

- ⊗ **New drug development:** Herceptin® (trastuzumab) is a monoclonal antibody developed to treat breast cancer that over-expresses HER2 (human epidermal growth factor receptor 2). This characteristic “is associated with an aggressive phenotype, high recurrence rate and reduced survival”¹¹⁶ and it affects approximately 25-30% of breast cancer patients.¹¹⁷ Before a drug could even be conceptualized, the HER2 protein had to be detected and reliably identified, and many breast cancers had to be analyzed to discover the proportion with overexpressed HER2. Then, the search for a drug targeted to this trait could begin. Ultimately, trastuzumab was developed, tested, and validated in research trials as an effective treatment for breast cancers that over-express HER2; its ability to work with other chemotherapeutic agents was also assessed. Two cost-effective screening tests were developed and are now available—immunohistochemistry (IHC—appropriate as a general screening tool for all breast cancer) and fluorescence in situ hybridization (FISH—used as further screening for patients with 2+ and 3+ IHC scores).¹¹⁸ And “...five recent adjuvant breast cancer trials have demonstrated an astonishing and highly reproducible benefit in halving the recurrence rate and reducing mortality in patients with this phenotype.”¹¹⁹
- ⊗ **Existing drug specifications:** Warfarin, an effective anticoagulant in use for many decades, has “a narrow therapeutic range because of both genetic and environmental factors,”¹²⁰ and has been under-prescribed because of “historically high rates of drug-associated adverse events.”¹²¹ Understanding these factors sufficiently well to alter dosing appropriately would enable this cost-effective drug to be used more widely. Studies assessing the role of patient demographics and known variants in CYP2C9 alleles and VKORC1 genotypes have been performed, and therapeutic response to warfarin is now known to vary among Jewish (both Ashkenazi and Sephardic origins), African American, and Asian patients.^{122, 123, 124} In 2005, “the U.S. FDA Clinical Pharmacology Sub-Committee (CPSC) of the Advisory Committee for Pharmaceutical Science voted to re-label the dosing of warfarin to take into consideration the new information.”¹²⁵ It is not known how many patients already on warfarin have undergone testing to re-evaluate their dosage since the prescribing recommendations were changed. However, at least one study has determined that “prospective application of a multivariate CYP2C9 gene-based warfarin dosing model is feasible,”¹²⁶ and another reported that “a quantitative dosing algorithm incorporating genotypes for 2C9 and VKORC1 could substantially improve initial warfarin dose-selection and reduce related complications.”¹²⁷

The incorporation of nutrigenomics (the effect of diet on gene expression), nutrigenetics (effect of genetics on response to diet, foods, or nutrients), proteomics, and metabolomics into the personalized medicine model has moved much more slowly,^{128, 129} perhaps simply as a reflection of the marked dominance of drug treatments that characterizes our healthcare system and shapes the funding priorities (see Sidebar in Chapter 2). However, much that is learned in pharmacogenomics will drive the knowledge base in these related fields as well because the underlying principle is common to all: individual genetic variations affect our physiological and biochemical response to virtually everything we are exposed to. This represents a fundamental alteration in our understanding of health and disease. The knowledge of how to identify and manage these individual differences is acutely needed for lifelong prevention of chronic disease. It won't be enough to say “Eat more vegetables and less fat and sugar.” We will need to be able to individualize

healthy diets, add targeted nutraceuticals, prescribe specific exercise programs, advise stress reduction efforts, plan to avoid certain pollutants, all based on individual genetic variations. Ultimately, personalized medicine will not be fully realized until all the influences, effects, and interactions are researched and described in such a way that practitioners are able to bring them to bear on an individual patient's health and on lifelong prevention of chronic disease.

Strengths and weaknesses

The ultimate promise of personalized medicine is its potential to uncover “the causes of the causes” of disease.¹³⁰ From the unlocking of the human genome to the development of proteomics (wherein we begin to understand how the proteins made by genes behave¹³¹), scientists can now demonstrate how individualized both health and disease really are. It's a powerful and exciting model that is already beginning to affect both research and clinical practice. Its strength is the rapidly developing science (all the –omics) that opens new vistas and new possibilities for dramatically increasing the effectiveness of individualized prevention and treatment strategies.

On the other hand, the many challenges of transferring this model to clinical practice are daunting; they include:

- ⊕ The “clinical complexity of genomic-based diagnostics and treatment.”¹³² A recent NIH report phrases the complexity question clearly: “An enormous scientific challenge now presents itself: What are the best ways to understand, prevent, and treat common, chronic diseases like heart disease, cancer, addiction, and mental illness when it is apparent that they are the result of interactions between individuals—in all their biological complexity—and their ever-changing physical, behavioral, and societal environments?”¹³³
- ⊕ Excessive cost¹³⁴
- ⊕ Regulatory issues^{135, 136}
- ⊕ Ethical concerns¹³⁷
- ⊕ The need for new information technology¹³⁸

At the level of patient care, additional complex challenges arise that may take decades to resolve:

- ⊕ Devising accurate and cost-effective genomic and/or proteomic screening tools
- ⊕ Identifying biomarkers that will indicate whether/when an active adverse process is in play for specific conditions in a given patient
- ⊕ Testing and validating diagnostic tools across many populations
- ⊕ Selecting appropriate patients for screening and demonstrating the usefulness of screening in improving patient outcomes through long-term clinical trials
- ⊕ Convincing third-party payers to reimburse for screening tests (likely to happen only when the results from long-term trials demonstrate cost-effectiveness)
- ⊕ Interpreting individual patient screening reports appropriately
- ⊕ Devising and validating effective interventions based on individual screening results

Common ground with other emerging models

As shown in Figure 2 (Chapter 1), personalized medicine shares many features with other emerging models: the emphasis on discovering individual patients' genetic vulnerabilities, the vision of individualized diagnostics and treatment, and the reliance on a powerful (and still emerging) scientific evidence base. It also shares with other models the absence of a clear and practical method of integrating emerging information into medical education and practice. Nor does it address structural and multidisciplinary issues in clinical practice that are part of the chronic-care model and integrative medicine.

Role in a synthesized, comprehensive model of 21st century medicine

Despite the rapidly evolving research base, therefore, personalized medicine does not (yet) have a robust, consistent architecture for clinical applications, nor does it describe a clear pathway toward achieving that goal. Research designs are still in development, and research findings do not specify how personalized medicine may (or may not) contribute to a new model of care for chronic disease. Even when a gene mutation, or SNP, can be identified, we may still be “six degrees of separation removed from the functional aspects of the disease,”¹³⁹ because gene analysis does not tell us which protein and protein pathways are affected and what the aberrant protein is doing. “Proteins are actually the drug targets; analysis of genes and gene expression just gives an indication of whether or not the proteins may be present.”¹⁴⁰ The same can be said of the effects of diet, environmental toxins, psychosocial influences, and many other lifestyle and environmental factors on gene expression and protein function. For these reasons, it is difficult to plan for the integration of this model into medical education in a systematic way in the near future.

It will be necessary, therefore, to ensure that whatever transformative model is used, it will allow clinicians to integrate new and useful information from personalized medicine as and when it becomes available, and will also empower them to respond effectively now to the urgent need for improved prevention and management of complex, chronic disease. Perhaps the single most valuable portion of the personalized medicine model at the moment is the transparency it brings to the concept of patient individuality. The evidence clearly reveals that each patient is a unique individual—one whose gene expression patterns are constantly in flux and whose complex and ever-changing response to treatment, environment, and lifestyle will challenge physicians to listen differently, see differently, and respond differently than taught by the linear model of acute care.

Prospective Medicine

“The ability to identify those individuals most at risk for developing chronic diseases and to provide a customized means to prevent or slow that progression are emerging competencies and provide the foundation for prospective care.”

—RALPH SNYDERMAN, MD AND R. SANDERS WILLIAMS, MD ¹⁴¹

What is it?

A relatively new concept introduced in 2003, prospective medicine is a descriptive rather than a prescriptive term, encompassing “personalized, predictive, preventive, and participatory medicine.”¹⁴² Snyderman argues persuasively that a comprehensive system of care would address not only new technologies (e.g., identification of biomarkers, use of electronic and personalized health records), but also delivery systems, reimbursement mechanisms, and the needs of a variety of stakeholders (government, consumers, employers, insurers, and academic medicine). Prospective medicine does not claim to stake out new scientific or clinical territory; instead, it focuses on creating an innovative synthesis of technologies and models—particularly personalized medicine (the “-omics”) and systems biology—in order to “determine the risk for individuals to develop specific diseases, detect the disease’s earliest onset, and prevent or intervene early enough to provide maximum benefit. Each individual would have a personalized health plan to accomplish this.”¹⁴³

Strengths and weaknesses

A very compelling element of prospective medicine is the call for fundamental change in clinical practice—from treating people only when they are sick enough to visit the doctor’s office to prospectively examining individual risks and developing comprehensive preventive strategies based on the best available evidence at the time. This would, indeed, revolutionize medicine; not only would it shift the focus of primary care, but it would establish a serious partnership between patient and clinician aimed at lifelong health. Snyderman emphasizes the need for clinical medicine and the emerging genomic models to integrate their respective knowledge and skills to create the best outcomes for patients. He discusses some diagnostic and risk-assessment tools that are already available, such as the following examples:

- ⊗ Know Your Number®, a program that “uses ... synthesis modeling to quantify an individual’s risk of developing chronic, preventable, obesity-related diseases such as diabetes, chronic obstructive pulmonary disease, and heart disease. In addition, KYN calculates what modifiable factors are contributing to that risk so that individuals can take steps to improve their overall risk profile.”¹⁴⁴ Although Know Your Number is not available directly to consumers, other similar programs are. One example is Navigenics Health Compass,¹⁴⁵ offering “A scan of your whole genome, carried out by a government-certified laboratory, that captures data on 1.8 million of your genetic risk markers.” For \$2500, individuals can obtain an analysis of their “genetic predisposition for a variety of common health conditions, and the information, support and guidance to know what steps you can take to prevent, detect or diagnose them early.” For \$250 per year, they will have a subscription that entitles them to regular updates.
- ⊗ Biomarkers can be assessed through an analysis of 250 serum proteins (\$3400). According to the company’s Web site: “Biophysical250 ... measures 250 different biomarkers that may indicate the presence of diseases and conditions often before symptoms appear. Unlike standard physicals

that measure only up to 40 biomarkers, Biophysical²⁵⁰ simultaneously assesses hundreds of biomarkers used by 12 different medical specialties.”¹⁴⁶

- Two gene-expression assays that predict recurrence of breast cancer in patients with stage I or II node-negative breast cancer. These tests can be used to individualize follow-up treatment by helping to determine “the need for systemic adjuvant therapy in such patients.”¹⁴⁷

Also compelling is the call to involve a broad range of stakeholders to “work together to develop innovative applications of new technologies and appropriate delivery models.”¹⁴⁸ It is certainly true that reimbursement strategies and academic training practices will have to evolve to encompass such a broad-based new model of care, and retraining existing practitioners must become a high priority.

What’s missing? Like the other emerging models we are discussing, prospective medicine does not provide a clear road map for integrating these new technologies into clinical practice. Precisely how, one wonders, will the 500,000+ MDs and DOs already in practice be retrained? How will academic medicine evolve? How many patients can spend \$2500-\$3500 on laboratory tests to assess risk biomarkers? How much new and expensive testing is actually necessary compared to how much risk is already clear when a comprehensive history is taken and a thorough examination including (mostly) standard laboratory tests is performed? And what, exactly, will change in clinical practice once expanded information is in hand from these new technologies? Will doctors still be in the same position they are in today—suggesting better diet, losing weight, and reducing stress without knowing how to help their patients make all of that happen?

The big missing piece in prospective medicine (at least as described thus far in the literature) lies in the absence of a clear, practical, and systematic method for altering clinical practice. Recognizing that the interactions between doctor and patient and between patients and their lifestyle-environment exposures and choices are where real change happens, Johns and Brigham,¹⁴⁹ offer this commentary on a post-prospective medicine world:

This “next *next* transformation” will identify “healthy” biologic processes (i.e., homeostatic) and provide tools for measuring early deviations from health (“unhealth”) that are not necessarily disease specific but that predict dire outcomes and warrant health-focused interventions. For example, many chronic diseases (diabetes, atherosclerosis, autoimmune diseases) share inflammation as a common mechanism. Characterizing an individual inflammatory phenotype may be a potent health predictor. And inflammatory responses to stress can be modified by behavior. Such health-focused treatment is the logical step beyond the “next transformation” that Snyderman and Yoediono advocate.

Common ground with other emerging models

Prospective medicine urges the integration of the developing sciences of personalized medicine and systems biology with the skills and knowledge of clinicians, and describes recommendations for revisions in reimbursement mechanisms and medical education that will be required in order to implement a comprehensive new system of care. It clearly relies on the emerging evidence base, but not to the exclusion of other important information. It does not specifically address the chronic-care model, nor issues of integrated care or integrative medicine; neither diagnostic approaches nor treatment strategies appear to include a multidisciplinary model of care.

Crossing the Quality Chasm

The Institute of Medicine's report, *Crossing the Quality Chasm*,¹⁵¹ comments extensively on the unmet needs of those with chronic conditions:

- » **Page 4:** "... there remains a dearth of clinical programs with the infrastructure required to provide the full complement of services needed by people with heart disease, diabetes, asthma, and other common chronic conditions (Wagner et al., 1996). The fact that more than 40% of people with chronic conditions have more than one such condition argues strongly for more sophisticated mechanisms to communicate and coordinate care (The Robert Wood Johnson Foundation, 1996)."
- » **Page 9:** "Care for the chronically ill needs to be a collaborative, multidisciplinary process."
- » **Page 28:** "In a population increasingly afflicted by chronic conditions, the health care delivery system is poorly organized to provide care to those with such conditions."
- » **Page 29:** "Thus the American health care system does not have well-organized programs to provide the full complement of services needed by people with such chronic conditions as heart disease, cancer, diabetes, and asthma."
- » **Page 89:** "Common chronic conditions should serve as a starting point for the restructuring of health care delivery because, as noted in Chapter 1, chronic conditions are

Role in a synthesized, comprehensive model of 21st century medicine

Because prospective medicine relies on personalized medicine and systems biology for the science of risk-assessment, many of its strengths and its limitations are found in those two models. It is, however, more comprehensive in sweep than either of them, incorporating not only technologies such as electronic health records but also acknowledging the need for simultaneous reform of the reimbursement structure and the training of future physicians. Thus, it is an important step forward, but it still lacks a robust, consistent architecture for clinical applications.

Chronic-Care Model

What is it?

The chronic-care model (CCM) is briefly outlined in Chapter 1 and fairly thoroughly described in the Appendix, where extensive material from the Improving Chronic Care Web site is included. The primary focus of this model is to include "...the essential elements of a healthcare system that encourage high-quality chronic disease care.... the community, the health system, self-management support, delivery system design, decision support and clinical information systems. Evidence-based change concepts under each element, in combination, foster productive interactions between informed patients who take an active part in their care and providers with resources and expertise."¹⁵⁰ The CCM is a response to powerful evidence that patients with chronic conditions often do not obtain the care they need, and that the healthcare system is not currently structured to facilitate such care (see **Sidebar**).

Strengths and weaknesses

The chronic-care model has the advantage of having been around for more than a decade; it has undergone considerable testing and revision. Implementation trials have indicated that, when enough of the model can be implemented, compliance with current algorithms and guidelines can be improved for conditions such as diabetes,^{152, 153} depression,¹⁵⁴ and tobacco cessation.¹⁵⁵ The CCM is a structure-of-care (or process-of-care) more than a content-of-care model; it describes a

multidisciplinary, multi-stakeholder approach to delivering care that will improve both patient and practitioner compliance with current evidence-based best practices. For this reason, integrating new technologies, such as those emerging from personalized medicine, are not explicitly addressed; one might assume that as those tools make their way into clinical guidelines and algorithms, they will become part of the CCM as well. However important improving the structure of care may be—and we certainly agree that it is important—the care thus provided will still be limited to the current medical model, which does not address individualizing care, lifelong primary prevention, or reversal of chronic disease, and which is primarily pharmaceutical in nature. We could imagine implementing, for example, personalized medicine using the chronic-care model, but no mechanism for achieving that is described. In fact, just implementing the full CCM itself is a very difficult proposition that encounters many barriers (e.g., no consensus on the value of the changes, limited change management skills within organizations, too many competing priorities, and failure to engage the commitment of physicians).¹⁵⁶ The Academic Chronic Care Collaborative, representing 22 academic medical centers, has reported some initial promising outcomes from their experiences with implementing aspects of the CCM.¹⁵⁷ It is worth noting that these institutions were committed to providing effective leadership and resources for the change process. The Agency for Healthcare Research and Quality provides an extensive *Toolkit for Implementing the Chronic Care Model in an Academic Environment*.¹⁵⁸

Common ground with other emerging models

The CCM shares with integrative medicine an emphasis on a multidisciplinary care model, the use of evidence-based best practices, and engagement of the patient in self-care. It does not address biochemical and physiological individuality, any of the emerging genomic technologies, or the influence of underlying mechanisms of disease. It shares with prospective health care a focus on structural, system-wide change, although the two models emphasize different aspects of structural change.

now the leading cause of illness, disability, and death in the United States, affecting almost half of the population and accounting for the majority of health care resources used (Hoffman et al., 1996).”

- » **Page 94:** “Four chronic conditions (cardiovascular disease, cancer, chronic obstructive pulmonary disease, and diabetes) account for almost three-quarters of all deaths in the United States (Centers for Disease Control and Prevention, 1999).”
- » **Page 211:** “The ability to plan care and practice effectively using multidisciplinary teams takes on increasing importance as the proportion of the population with chronic conditions grows, requiring the provision of a mix of services over time and across settings.... A changing relationship between clinicians and their patients also calls for new skills in communication and support for patient self-management, especially for patients with chronic conditions. Collaborative management requires collaboration between clinicians and patients in defining problems, setting goals, and planning care; training and support in self-management; and continuous follow-up (Von Korff et al., 1997). Patients with chronic conditions who are provided with knowledge and skills for self-management have been shown to experience improvements in health status and reduced hospitalizations (Lorig et al., 1999). Clinicians need to have skills to train

Crossing the Quality Chasm, *continued*

patients in techniques of good self-management.”

- » **Page 237:** “Patients with chronic conditions, for which certain routine examinations and tests are crucial in order to prevent complications, do not all get the care they need.”

Note: Citations included in the above quotations are available in the Institute of Medicine report, but are not provided here.

Role in a synthesized, comprehensive model of 21st century medicine

The CCM advances our knowledge of how to improve the structure or process of care for chronic disease using standard approaches, but it does not advance our ability to select more effective strategies for actually improving both treatment and prevention. Still lacking is a robust, consistent architecture for selecting the most effective clinical applications for each unique patient.

Evidence-based Medicine (EBM)

What is it?

EBM is a tool for improving clinical practice. Its stated goal is to ensure that clinical decision making is grounded in the best available evidence. Despite its many limitations, it wields a great deal of power over medical training, clinical practice, and—increasingly—reimbursement decisions and legal determinations.^{159, 160} We include it in our discussion of emerging models because of its multifaceted influences on patient care. Although it is beyond the scope of this paper to explore EBM in depth, it is critical to the future of health care to understand its strengths and weaknesses. To that end, we provide a brief description of this evolving paradigm.

Since the late 1970s, various efforts have been made to systematize the use of research findings in clinical decision making.¹⁶¹ Rather than expecting each practitioner to establish and maintain a constant surveillance over a rapidly expanding evidence base, and to know which studies should generate the highest level of confidence, specific guidelines have been proposed concerning the interpretation of evidence that influences clinical decision making. There have been many definitions and ratings of what constitutes poor, good, and best evidence, but in the early 1990s, the term evidence-based medicine appeared for the first time,^{162, 163} reflecting an increasing consensus that a more standardized approach to the use of medical evidence was on the way. Early efforts sought explicitly to reduce “...the emphasis on unsystematic clinical experience and pathophysiological rationale” while promoting “the examination of evidence from clinical research.”¹⁶⁴

A hierarchy of evidence reliability was proposed, with meta-analyses and systematic reviews at the top and personal communications at the bottom (see Figure 6). Over the years, this hierarchy has been revised and adapted many times for a number of reasons:

- ⊕ It did not identify a mechanism for decreasing or increasing an assessment of value based upon, for example, study size, adequacy of blinding, bias, directness of the evidence, and other factors.¹⁶⁵
- ⊕ It failed to accommodate many important criteria for translating evidence into clinical practice—for example, the degree to which outcomes being tested were important to patients, whether results were consistent with past studies, and whether confidence intervals were overly broad.¹⁶⁶
- ⊕ It inappropriately identified systematic reviews and meta-analyses as evidence (they are, rather, interpretations of the evidence and should be produced, at least in part, based on EBM principles).^{167, 168}
- ⊕ It did not differentiate between quality of evidence and strength of recommendations. “High quality evidence doesn’t necessarily imply strong recommendations, and strong recommendations can arise from low quality evidence.”¹⁶⁹

One example of a subsequent adaptation is provided in Figure 7, where we can see that other useful criteria were added to the model, altering the earlier and more simplistic assessment of evidence usefulness.¹⁷⁰

The basic concepts have continued to evolve. “In 2000, the Evidence-Based Medicine Working Group presented the second fundamental principle of EBM (the hierarchy of evidence being the first): Whatever the evidence, value and preference judgments are implicit in every clinical decision. A key implication of this second principle is that clinical decisions, recommendations, and practice guidelines must not only attend to the best available evidence, but also to the values and preferences of the informed patient.”¹⁷¹

A major advance over the use of any hierarchy, however complex, has been the development of the GRADE (Grading of Recommendations Assessment, Development and Evaluation) system. Figure 8 shows a partial representation of this system; in practice, it has other important elements as well. The GRADE system describes a very sophisticated, multi-level evaluation of evidence; its purpose is to strengthen recommendations for clinical practice and to increase confidence in those recommendations. Because of its complexity, however, it is not intended for use by individual clinicians, who generally have neither the time nor the expertise to implement it. It is aimed primarily at researchers and clinical guideline developers, who have not heretofore used a consistent and uniform methodology that is transparent to all potential users.¹⁷² GRADE software is now available for free at the GRADE Working Group’s Web site,¹⁷³ making it even more likely that its use will continue to expand.

Figure 7:
Hierarchy of Evidence (Evans)

A. Criteria for Assigning Level of Evidence	
Type of Evidence	
Randomized trial	High
Observational study	Low
Any other type of research evidence	Very Low
Increase level if:	
Strong association	(+1)
Very strong association	(+2)
Evidence of a dose-response gradient	(+1)
Plausible confounders reduce observed effect	(+1)
Decrease level if:	
Serious or very serious limitations in quality	(-1) or (-2)
Important inconsistency	(-1)
Some or major uncertainty about directness	(-1) or (-2)
Imprecise or sparse data*	(-1)
High probability or reporting bias	(-1)
B. Definitions for levels of evidence	
High Further research is not likely to change our confidence in the effect estimate	
Moderate Further research is likely to have an important impact on our confidence in the estimate of effect and may change the estimate	
Low Further research is very likely to have an important impact on our confidence in the estimate of effect and is likely to change the estimate	
Very Low Any estimate of effect is uncertain	
*Few outcome events or observations or wide confident limits around an effect estimate	

Figure 8:
Overview of the GRADE System for Evaluating Evidence (Bagshaw)

Over the years, a number of studies have verified that teaching EBM will, in fact, significantly increase the degree to which practitioners apply it.¹⁷⁴ Training is more successful if it is both experiential and didactic.^{175, 176, 177} Unfortunately, there are very few studies available as yet that tell us whether EBM improves overall patient health over a period of years.

Strengths and weaknesses

There can be little doubt that a thoughtful evaluation of evidence is an indispensable factor in delivering high-quality health care. The emergence of formal assessment processes reflects a desire to establish greater clarity and confidence about the reliability of evidence. Even a casual user of Medline or PubMed

quickly becomes aware of the overwhelming quantity of published research available today; it is a daunting prospect to identify the best or most relevant papers among hundreds or thousands that may be available on a particular topic. For example, a PubMed search for the phrase *evidence-based medicine* in titles and abstracts returns nearly 5000 entries encompassing dozens of journals! There are, of course, tools for narrowing a search term or process, but it is still inordinately time consuming to obtain, read, evaluate, and then compare even a few individual research papers on a specific subject. Such a process, even if an EBM hierarchy is used, is also subject to a great deal of individual bias. Thus, any tool that provides significant and reliable assistance in such an endeavor is welcome, and that is one of the primary rationales for the development of clinical guidelines.^{ix}

As the use of EBM has become increasingly widespread, its limitations and weaknesses have also become more apparent. Paramount among the problems is that EBM reflects an acute-care model: it most often assumes that the goal of care is a single diagnosis followed by a hierarchy of (primarily) single-agent treatments. Although GRADE has made an admirable attempt to compensate for many EBM weaknesses, these fundamental goals remain the gold standard. Therefore, EBM fails at the same point where the research itself fails—in its inability to account for unique patient geno/phenotypes, multiple comorbidities, and personalized approaches to care that include multiple interventions for complex, chronic disease. Such multifaceted interventions may include dietary, nutraceutical, pharmaceutical and/or surgical recommendations, as well as many options from the natural medicine world (e.g., botanical medicine, acupuncture and oriental medicine, body/mind practices).

EBM and any guidelines derived from applying an EBM model to the evidence are, of course, only as good as the underlying research, which presents several problems:

- ⊕ Not only is the research agenda disproportionately driven by the pharmaceutical industry, but it is tainted by the failure to publish negative or neutral results and by industry bias (see Chapter 2).
- ⊕ Much of generally accepted medical practice has not been systematically evaluated. For example: “Of around 2500 treatments covered [in *BMJ Clinical Evidence*] 13% are rated as beneficial, 23% likely to be beneficial, 8% as trade off between benefits and harms, 6% unlikely to be beneficial, 4% likely to be ineffective or harmful, and 46%, the largest proportion, as *unknown effectiveness* [italics added].”¹⁷⁸
- ⊕ Individuals studied in RCTs do not reflect the patient population seen most often in primary care; confidence in the transferability of the data is thereby reduced.¹⁷⁹
- ⊕ “Randomized trials, especially if evaluating complex interventions or with strict inclusion/exclusion criteria, often only provide data in a clinical context that does not exist outside the trial itself and have limited power to detect harm.... Systematic reviews require vigilant interpretation and should not necessarily be considered as high level evidence due to issues related to ... incomplete reporting and the inclusion of evidence from trials of poor quality.... Meta-analyses are not primary evidence; they are statistically assisted interpretations of

^{ix}Clinical guidelines are “systematically developed statements to assist practitioner and patient decisions about appropriate health care for specific clinical circumstances”—Institute of Medicine, 1990. “They define the role of specific diagnostic and treatment modalities in the diagnosis and management of patients. The statements contain recommendations that are based on evidence from a rigorous systematic review and synthesis of the published medical literature”—<http://www.nhlbi.nih.gov/guidelines/about.htm>.

primary evidence. They have been shown to contradict confirmatory trials, especially when such meta-analyses are based upon small, low quality studies.”¹⁸⁰

- ⊛ “Even the most promising findings of basic research take a long time to translate into clinical experimentation, and adoption in clinical practice is rare.”¹⁸¹ Evidence-based guidelines of genomic applications are even more rare, and thus are unavailable to practitioners who rely on EBM processes to update their clinical practices.¹⁸²

Common ground with other emerging models

EBM is, to differing degrees, part of all the other models described in this paper. Since EBM focuses primarily on mechanisms for translating research findings into clinical applications, it is less useful for those aspects of personalized medicine and systems biology that concentrate on the basic research itself. Also, as noted above, integrating personalized assessment and treatment with EBM models is not yet feasible on a systematic basis. It will be extremely interesting to see whether this can be done.

Role in a synthesized, comprehensive model of 21st century medicine

In our opinion, the role of EBM is strongest in acute-care situations, where the physician or healthcare team must focus on short-term and fairly narrowly defined issues. When we consider its role in outpatient primary care for complex, chronic disease, however, it is more difficult to make an overall determination of usefulness. Certainly there are situations where EBM and the clinical guidelines that flow out of it are extremely useful. In general, however, it seems easier to see the problems (described above) than it is to detect the benefits. Nonetheless, there is great benefit to researchers, practitioners, and patients in improving our ability to objectively and systematically evaluate data and determine clinical usefulness. Overall, this is perhaps the most important role that EBM will play over time.

Systems Biology

What is it?

Although there is not yet a universally recognized definition of systems biology, the National Institute of General Medical Services (NIGMS) at NIH provides the following explanation: “A field that seeks to study the relationships and interactions between various parts of a biological system (metabolic pathways, organelles, cells, and organisms) and to integrate this information to understand how biological systems function.”¹⁸³ The *Molecular Systems Biology Blog on Systems & Synthetic Biology* poses—and provides some possible answers to—the question of why it appears to be difficult to come up with a concise and generally applicable definition: “One of the reasons might be that every definition has to respect a delicate balance between ‘the yin and the yang’ of the discipline: the integration of experimental and computational approaches; the balance between genome-wide systematical approaches and smaller-scale quantitative studies; top-down versus bottom-up strategies to solve systems architecture and functional properties.” The blog hypothesizes that, “despite the diversity in opinions and views, there might be two main aspects that are conserved across these definitions: a) a system-level approach attempts to consider *all the components*

of a system; b) the properties and interactions of the components are linked with functions performed by the intact system via a *computational model*.”¹⁸⁴

We would add to the NIGMS definition that it is also vital to understand how the human system interacts with the environment, as well as how all the components act and interact. We see systems biology as a broad term for the basic science underlying the personalized medicine revolution (described above). While the fields of personalized, prospective, and integrative medicine all recognize (to varying degrees) the importance of nutritional genomics, pharmacogenomics, metabolomics, and proteomics to the future of health care, most of the scientific research has been generated by systems biologists (whether or not they identify with that term or any of the many definitions proposed). Thus far, although systems biology *claims* virtually the same broad territory as personalized medicine, it actually *focuses* almost exclusively on pharmacogenomics—in the Willie Sutton idiom, “That’s where the money is.” Attention to the applicability of those findings to patient care (i.e., the gene-environment interaction that creates the phenotype) is what connects systems biology to personalized medicine.

Strengths and weaknesses

Identifying the nature and effects of the myriad interactions that occur where human biology is exposed to the environment is almost unimaginably complex. Yet that effort is critical to a better understanding of the multifactorial nature of disease development. We know that “the causes of most chronic diseases will require an understanding of both the genetic and environmental contribution to their etiology.... The most critical issue is how to relate exposure-disease association studies to pathways and mechanisms.... Scientists will need tools with the capacity to monitor the global expression of thousands of genes, proteins and metabolites simultaneously.... Even when all the highly relevant genes and their interactions with specific environmental components have been identified, it will still be difficult to relate the influence of an individual’s genotype to their disease phenotype due to the added complexity of gene-gene interactions, post-translational processing, and protein-protein interactions.”¹⁸⁵

Because of the magnitude and complexity of the challenge, “Systems biology research should create an interactive inter-disciplinary scientific culture. For progress to occur, experts in engineering, physics, mathematics, and computer science must join biochemists, cell biologists, and physiologists in the effort to figure out how to obtain the required data and develop the sophisticated computational approaches that will be needed to make viable predictions.”¹⁸⁶ This is a long-term prospect, of course, although early studies have shown some highly beneficial outcomes of genomic medicine¹⁸⁷ (a plausible term for applying the findings of systems biology to patient care).

Many of the same obstacles discussed earlier in this chapter vis-à-vis personalized medicine and pharmacogenomics¹⁸⁸ are inherently shared by systems biology. In addition to barriers of cost, complexity, equipment, ethics, and education, “the evidence and importance of most pharmacogenomics associations are not sufficient to overcome the barriers to clinical implementation.... It is likely that complementary technologies, such as metabonomics, will be able to compensate for some limitations of genotype-phenotype association.”¹⁸⁹

Common ground with other emerging models

Systems biology seeks to elucidate the biological underpinnings of disease risk and apply that knowledge within a personalized, predictive, prospective, and participatory model of patient care. The science of systems biology clearly underlines the congruent goals of personalized medicine, prospective medicine, and—to a lesser extent—integrative medicine. It is not entirely congruent with evidence-based medicine, because it has not yet generated a large number of clinical trials. In fact, systems biology somewhat reverses the direction of EBM described above, in that it takes us back to a more “pathophysiological rationale” of disease and treatment. Eventually, research models will be devised to test the effectiveness and reliability of patient care based on diagnostic tests and therapeutic recommendations derived from systems biology.

Role in a synthesized, comprehensive model of 21st century medicine

Systems biology illuminates the science that will support a new model of health care—one that is based on an intimate understanding of complex human systems interacting with complex environments and unique genetic inheritances.¹⁹⁰ In order to achieve its greatest potential, it must broaden its scope far beyond pharmacogenomics, which represents a very small portion of what we need to know about preventing and treating complex, chronic disease.

Integrative Medicine

What is it?

“Integrative medicine can be defined as an approach to the practice of medicine that makes use of the best available evidence taking into account the whole person (body, mind, and spirit), including all aspects of lifestyle. It emphasizes the therapeutic relationship and makes use of both conventional and complementary/alternative approaches.”¹⁹¹ The field is now nearly 10 years old and it is the only one of the emerging models discussed in this paper to explicitly encompass the integration of therapeutics that, until recently, were the sole purview of complementary and alternative medicine^x (CAM). A number of forces are responsible for the emergence of this new discipline:

- The initial driver was undoubtedly the burgeoning interest in and demand for CAM displayed by consumers over many years. As reported in the *Annals of Internal Medicine* in 2001, “Use of CAM therapies by a large proportion of the study sample is the result of a secular trend that began at least a half century ago. This trend suggests a continuing demand for CAM therapies that will affect health care delivery for the foreseeable future.”¹⁹²
- The establishment of the NIH National Center for Complementary and Alternative Medicine (NCCAM) provided research funding to investigate CAM therapies. As research into CAM therapies revealed many effective natural (nonpharmaceutical, nonsurgical) approaches to

^xA widely used definition of CAM therapies from the Osher Institute at Harvard: “clinical services not routinely used within conventional care, such as chiropractic, acupuncture, massage therapy, homeopathy, meditation, music therapy, therapeutic touch, yoga, Reiki, and advice involving herbal products and other dietary supplements.”

Meditation and Brain Science

Meditation may be one of the best studied body-mind modalities. The effects of meditation on the brain have been studied using sophisticated functional MRI (fMRI) and electroencephalographic (EEG) techniques. Not only have researchers detected significant differences in brain activity between experienced meditators and nonmeditators (or inexperienced meditators), but there also may be detectable differences resulting from the particular type of meditation studied.¹⁹⁹ Although more substantial differences can be found with long-term meditators, even a short training period of eight weeks “produces demonstrable effects on brain and immune function.”²⁰⁰ Some findings suggest that “the resting state of the brain may be altered by long-term meditative practice,” and that “attention and affective processes...are flexible skills that can be trained.”²⁰¹ The practical implications of such findings, if replicated on a large scale, could be considerable. One report concluded that “it is plausible from our results that meditation may strengthen the ability to inhibit cognitive and emotional mental processes such as rumination that can lead to or exacerbate stress, anxiety, or depression.”²⁰² A subsequent study to test this hypothesis returned startling results²⁰³:

MBCT [mindfulness-based cognitive therapy] was more effective than m-ADM [maintenance antidepressant medication] in reducing residual depressive

a wide variety of diseases and conditions, it was thought desirable for physicians to understand CAM in much greater depth¹⁹³ and to devise a pathway for validated approaches to be brought into the standard “medicine chest.”¹⁹⁴

- ⊗ The philanthropic funding of centers and departments of integrative medicine within the academic medicine community (e.g., University of Arizona, Harvard, Vanderbilt, Duke; also see list in the Appendix of members of the Consortium of Academic Health Centers for Integrative Medicine) brought high-level attention to the educational element: “Integration of CAM with conventional health care requires educational venues that prepare conventionally trained caregivers with a sufficient knowledge base for assessing beneficial and detrimental interactions between CAM and conventional care approaches; development of criteria for making informed referrals to CAM practitioners; and enhanced research capacity.”¹⁹⁵
- ⊗ Integrative medicine might also be characterized as a response to the increasing depersonalization of health care that came with the rise of HMOs, greater use of technology, decreasing time spent in the outpatient visit, and the insertion of third-party payers into the doctor-patient relationship.¹⁹⁶

Integrative medicine curriculums now commonly describe a fairly comprehensive set of core competencies that include dietary interventions, nutraceuticals, botanical medicines, body-mind practices (see, for example, **Sidebar** on meditation), energy medicine (e.g., acupuncture), and manual medicine (e.g., massage, chiropractic).^{197, 198} The balance of didactic knowledge (for the purpose of providing better-informed advice and referrals to patients) vs. practical skills (for actually integrating clinical applications) varies from program to program.

Strengths and weaknesses

Integrative medicine is an important step toward a functionally integrated healthcare system that includes all appropriately credentialed practitioners. Not only does it provide an avenue for validated CAM therapies to be more widely used, but it supports

the interdisciplinary team concept in both educational and clinical settings. It allows patients greater freedom of choice in both therapies and providers, and it encourages dialogue among all health practitioners.

There is a danger that integrative medicine physicians will extend their practices beyond the scope of their education. Completing a program in integrative medicine does not turn an MD or a DO into a trained chiropractor, acupuncturist, naturopathic physician, or other such practitioner. It is important that those who wish to fully practice an alternative discipline seek comprehensive training from accredited institutions, just as those who wish to practice as medical doctors must do.

Common ground with other emerging models

Integrated medicine uses evidence-based medicine to select the practices to integrate. It is multidisciplinary and oriented toward whole-person health care. It is the only one of the models to explicitly integrate alternative practitioners and approaches, to emphasize the importance of the practitioner-patient relationship, and to bring body-mind issues to the fore. Other than EBM, it is the only one that already has a significant foothold within academic medicine.

Role in a synthesized, comprehensive model of 21st century medicine

Integrative medicine provides great leadership in demonstrating the importance of a more integrated healthcare system and in creating academic models to educate practitioners in this new approach. It could benefit from a greater emphasis on genomic medicine, perhaps by incorporating some of the principles or recommendations of personalized or prospective medicine.

symptoms and psychiatric comorbidity and in improving quality of life in the physical and psychological domains. There was no difference in average annual cost between the two groups. Rates of ADM usage in the MBCT group was [sic] significantly reduced, and 46 patients (75%) completely discontinued their ADM. For patients treated with ADM, MBCT may provide an alternative approach for relapse prevention.

Chapter 4

THE CLINICIAN'S DILEMMA

*[W]hat we observe is not nature itself, but nature exposed to our method of questioning
Natural science, does not simply describe and explain nature;
it is part of the interplay between nature and ourselves.*

—WERNER HEISENBERG, PHYSICS AND PHILOSOPHY, 1958

We have spent, to this point, a great deal of time and effort exploring both the challenge of 21st century medicine—to first halt and then reverse the epidemic of chronic disease—and some of the most prominent among many proposed solutions. We hope we have achieved a shared recognition that our current tools and approaches are not sufficient to the task, and that changes in the practice of medicine are necessary and imminent. At the same time, we cannot ignore the challenge of making these conclusions relevant to the individual practice of medicine. For, ultimately, most health care is delivered one patient and one practitioner at a time. In this chapter, we explore the clinician's dilemma: how to practice in such a way that both the continuing advances of science and the essential art of medicine are integrated seamlessly into clinical practice, neither overshadowing the other. It won't matter how intelligent and persuasive the arguments for change may be if we cannot convert them into practical approaches that can be taught to and adopted by individual clinicians.

This paper is not intended as an exploration of the actual clinical interventions that comprise functional medicine nor of the extensive science that underlies them. For that purpose, we refer the reader to the books, monographs, and courses available through The Institute for Functional Medicine (IFM).^{xi} In these final two chapters, we address clinical practice at a different level, presenting the foundational concepts and principles that we believe should shape the coming changes in health care.

^{xi}A complete list of IFM publications and courses can be found at www.functionalmedicine.org.

The Central Hub of 21st Century Medicine

The primary principle around which 21st century medicine—functional medicine—will revolve is *personalized, systems medicine*. Grouping people into categories based on organ system diseases, and then prescribing as though all people with a given diagnosis were inherently alike, is beginning to give way to a model that recognizes each patient's genetic and environmental uniqueness. Clinicians must develop the knowledge and skills to deliver individually tailored care. They must be able (and willing) to incorporate the science of systems biology, the emerging discipline of personalized care, and a much broader array of assessment, therapeutic, and preventive strategies into a new therapeutic relationship.

Each human emerges from a mold that has but one model.^{xii} Uniqueness continues to develop throughout life as a result of myriad influences. Family, school, work, community, diet, exercise, stress, and environmental toxicity all communicate information from outside the organism to the epigenetic translational structures that are married to nuclear DNA and that create powerful downstream effects on the genome, proteome, and metabolome. This phenomenon of biochemical uniqueness was recognized, researched, and documented in the 20th century, and is the foundation from which many key constructs have evolved, including systems biology and systems medicine, prospective health care, patient-centered health care, nutrigenomics, pharmacogenomics, proteomics, and metabolomics/metabonomics (see Chapter 3).

Decision Making in the Face of Uncertainty

From this chaotic, nonlinear interplay of complex factors, involving the integration of both genetics and context of living, emerges the haunting reality that all care is provided in a context of uncertainty. This is the shadow side of modern clinical medicine and it poses a daunting conundrum—how do you structure and systematize the assessment and treatment of patients when each is the product of a multitude of unique genetic and environmental influences and interactions? Kathryn Montgomery in her scholarly book, *How Doctors Think*, directly addresses this challenging issue:

Complexity and uncertainty are built into the physician's effort to understand the particular in light of general rules.... The obstacle they encounter is the radical uncertainty of clinical practice: not just the incompleteness of medical knowledge but, more important, the imprecision of the application of even the most solid-seeming fact to a particular patient.²⁰⁴

What elevates the importance (and the stress) of clinical care over the work of, for instance, engineers, lawyers, accountants, and other nonclinical professionals is its continuous involvement in matters of life and death. The cost of failure is so high—death, when life might have been possible; illness, when health might have been attainable. The daily unconscious concern of every clinician is the weight of this cumulative decision making—inherently uncertain and lacking full (or sometimes even adequate) information to inform the clinical picture. Dr. Jerome Groopman in his provocative book with the same title, *How Doctors Think*, addressed this issue from his clinical perspective:

^{xii}The potential for human cloning might be considered the exception to this rule. However, exact replication from a clone donor cannot duplicate the pre and post epigenetic imprinting that skews the exactness of a clone.

Uncertainty creeps into medical practice through every pore. Whether a physician is defining a disease, making a diagnosis, selecting a procedure, observing outcomes, assessing probabilities, assigning preferences, or putting it all together, he is walking on very slippery terrain. It is difficult for non-physicians, and for many physicians, to appreciate how complex these tasks are, how poorly we understand them, and how easy it is for honest people to come to different conclusions.²⁰⁵

Personalized, systems medicine serves to inform us about the enormity of the uncertainty. The message is clear: there is no one-size-fits-all solution to resolve any specific diagnosis. The limitations of clinical algorithms and evidence-based medicine can now be more clearly discerned. We can no longer allow them to skew our understanding of the larger picture, however difficult it may be to look at unflinchingly. We are at a crossroads where only honesty about the limitations of strategies that seek to avoid or ignore uncertainty will suffice.

For the great enemy of truth is very often not the lie—deliberate, contrived, and dishonest—but the myth—persistent, persuasive, and unrealistic. Too often we hold fast to the clichés of our forbears. We subject all facts to a prefabricated set of interpretations. We enjoy the comfort of opinion without the discomfort of thought.

—JOHN F. KENNEDY, YALE COMMENCEMENT, 1962

Medicine has attempted historically, through a number of shifts in perspective, to provide greater certainty to both practicing clinicians and patients, a patently valuable goal. Setting aside traditional methods of instilling confidence—oracles or shamans, for example—science has been a very important tool for reducing uncertainty.

Twentieth century medicine completed a great philosophical and practical transformation into the *organ system* model of disease and diagnosis. This provided an evolving and reassuring sense of control and certainty as a result of ever-increasing specialization (often described as knowing more and more about less and less) as well as myriad fascinating scientific breakthroughs in understanding the nature of life, health, and disease. From early x-rays through the sophisticated imaging processes in use today, through ever more complex and detailed biochemical pathways, we have explored the silos of mammalian organ systems taxonomy. Objective facts accreted in uncountable numbers during the 1900s, describing human anatomy, physiology, and mechanisms of dysfunction from the cellular level to the specific organs themselves. The medical specialties (e.g., cardiology, neurology, nephrology) emerged and grew strong from these historic breakthroughs.

Near the end of the 20th century, however, the reality of the web-like, chaotic, nonlinear and complex nature of life (and health)—exposed by advances in the systems-oriented life sciences—began to erode this reassuring sense of certainty. Twenty-first century medicine has now come face-to-face with the practical implications of uncertainty—a problem that flummoxed many mid-20th century physicists (including the great Albert Einstein, who ultimately rejected what is now an accepted principle) when they first confronted Heisenberg's articulation of the principle of uncertainty in physics. Fortunately, once the seriousness of this issue is consciously acknowledged, management strategies can be developed. First, however, we have to stop denying the presence and power of uncertainty in medicine. Research by brain scientists using advanced imaging and electronic technologies and analytic techniques equips the clinician with important knowledge for facing squarely the daunting task of assessing and treating each patient as

a unique individual, shaped by innumerable complex interactions between genetics and the cumulative influences of daily life.

The rest of this chapter will discuss these findings and will describe why the context of uncertainty in medicine requires a change in our view of evidence and the therapeutic relationship, and a considerable expansion in the clinical tool kit of the practitioner. The increasingly technical (and increasingly brief) clinical encounter that has characterized the last few decades in medicine can be transformed into a *healing partnership* through the appropriate integration of relevant evidence from clinical trials, the knowledge gained from breakthroughs in brain science and systems biology, and an expanded clinical armamentarium. Within this complex relational system can be found effective strategies for individualized assessment and treatment, taking into account the uncertainty generated by the complex genetic and environmental uniqueness of each patient—we can, in fact, begin the practice of *personalized, systems medicine* today.^{206, 207}

Evidence-based Medicine in the Clinical Setting: Uses and Limitations

The scientific method disciplines the creative process of human inquiry. In the applied biological sciences (e.g., clinical medicine) prior to World War II, evaluation of emerging therapeutics was mainly the purview of recognized leaders in the medical profession, based primarily on their clinical experience and reputations, and without the rigor of systematic controls or external standards.²⁰⁸ To improve the quality of evidence and render a more accurate judgment with less personal bias, postwar researchers developed the randomized controlled trial (RCT) protocol. The major characteristics of this method include blinded assessment (of subjects, investigators, or both), often in the presence of a placebo control; random assignment to comparable groups; and inferential statistics as a surrogate for establishing causation.²⁰⁹

The reliance on the expert gave way to reliance on results from RCTs. Clinicians could no longer reduce uncertainty by following the lead of a confident expert, but they increasingly appreciated the power of the double-blind, randomized, placebo-controlled clinical trial—a step up in certitude.^{210, 211} Putting aside, for the moment, the many problems inherent in the RCT model, not the least of which is the bias introduced by the influence of big Pharma,^{212, 213, 214, 215} let's briefly explore EBM—the offspring of the RCT model—as understood and used by clinicians to reduce uncertainty.

Proponents of the RCT as the gold standard for unbiased research results have fostered its preeminence in the applied medical fields, both in primary and specialty care. They have argued for and developed algorithms for grading recommendations based on a research quality scale that ranks methodologies in descending order of accepted best evidence:^{216, 217}

- ⊗ Systematic reviews and meta-analyses of RCT studies
- ⊗ RCTs
- ⊗ Nonrandomized intervention studies
- ⊗ Nonexperimental studies
- ⊗ Expert opinion

Amid the early excitement generated by this new schema, certain assumptions were posited as foundational:

A new paradigm for medical practice is emerging. *Evidence-based medicine de-emphasizes intuition, unsystematic clinical experience, and pathophysiologic rationale as sufficient grounds for clinical decision making* and stresses the examination of evidence from clinical research. Evidence-based medicine requires new skills of the physician including efficient literature searching and the application of formal rules of evidence evaluating the clinical literature.²¹⁸ [Italics added.]

—EVIDENCE-BASED MEDICINE WORKING GROUP, JAMA, 1992

The application of EBM in the clinical setting is described as following this general scenario:^{219, 220}

- ⊗ Select specific clinical questions from the patient's problem(s)
- ⊗ Search the literature or databases for relevant clinical information
- ⊗ Appraise the evidence for:
 - validity against the hierarchy of evidence as described above, and
 - usefulness to the patient and practice
- ⊗ Implement useful findings in everyday practice

Arguments in favor of EBM infusion into both medical education and clinical practice are based on the following facts and inferences:^{221, 222}

- ⊗ Available new evidence can and should lead to major changes in patient care
- ⊗ Practicing physicians often fail to obtain available newer relevant evidence
- ⊗ Medical knowledge and clinical performance deteriorate over time without the leavening of newer evidence influencing clinical decisions
- ⊗ Traditional continuing medical education (CME) alone is inefficient and generally does not improve clinical performance without significant follow-up and evaluation measures
- ⊗ The discipline of using evidence-based medicine can keep clinicians up-to-date

In a cogent paper in *The Lancet* in 1999, van Weel and Kottnerus responded to the proddings of many eminent medical thought leaders to move ahead quickly and comprehensively with the integration of EBM into the clinical setting by pointing out the many difficulties of using this schema to manage the care of individual patients with complex, chronic illness:²²³

- ⊗ EBM tends to concentrate on research methodology and reduces clinical practice to the technical implementation of research findings. In a more colloquial view, it is the tail wagging the dog. Rather than using clinical judgment to guide the choice of relevant evidence, EBM is structured with a hierarchy of evidence as the driver of clinical judgment.

- ⊕ The structure of RCT methodology assumes the consequences of individual variability in response to treatment will “wash out” if the subject pool is large enough and the statistical analyses sophisticated enough. *While this may be true for populations, it seriously limits the applicability of the research in primary care, where therapy is delivered one unique patient at a time.*
- ⊕ Co-morbid conditions are the usual justified reason for the exclusion of many patients from RCTs, *so the very patients most in need of usable evidence (e.g., those with complex, chronic conditions) are often not in the cohorts of patients being studied*, making the findings from the research trials very limited in their applicability.
- ⊕ In primary care, treatment usually involves several interventions, sometimes delivered concurrently and sometimes sequentially. Unfortunately, combinations of evidence-based interventions do not sum to a treatment plan that is evidence-based. Interactions between single interventions may increase or decrease their efficacy (even under ideal trial conditions), when blended into a comprehensive plan. Adverse interactions among treatments may, and often do, occur.
- ⊕ Clinical research does not focus on the overall outcome of composite interventions because of the complexity of such studies and the absence of well-developed tools for studying such whole systems approaches.
- ⊕ Drug interventions have been studied more extensively than nonpharmacological interventions, in part due to the technical and methodological difficulties in the design of RCTs for nondrug interventions (and, in part, because of the nonpatentable nature of most lifestyle interventions). This situation creates a significant problem in primary care, where the use of educational, dietary, and lifestyle interventions is attractive because of their resonance with the principle of “maximum effect using minimum resources.”

In marked contrast to the assertions of the EBM Working Group cited earlier, van Weel and Knottnerus suggest that the driving force behind EBM should be a coherent system of fundamental research in *pathophysiology and the humanities*, combined with careful clinical observations, on which systematic (RCT-based) evidence of effectiveness is superimposed. Existing clinical practice should be supported or, if erroneous, corrected on the basis of this coherent system. They go on to propose that “two complementary approaches are needed to strengthen the evidence base of nonpharmacological interventions and complex multifaceted strategies. First, the generic characteristics of complex interventions must be acknowledged as essential for its evaluation. Second, a methodology to allow the assessment of complex effects should be further developed.”

Dr. David Mant in his seminal 1999 paper, “Can randomized trials inform clinical decisions about individual patients?” takes a slightly different tack in exploring the irony that the RCT combines strength of concept for the population being studied with weakness of specific application to the individual patient.²²⁴

The paradox of the clinical trial is that it is the best way to assess whether an intervention works, but is arguably the worst way to assess who will benefit from it.... However, the nub of the argument for me is that randomized controlled trials are primarily about medical interventions and not patients. In clinical trials, patients are randomized to allow a comparison of intervention efficacy unbiased by the individuality of patient. This methodological approach provides society with powerful protection against witch-doctoring, and helps us eliminate the inefficiencies in the provision of medical care described by Cochrane. *But the methodological minimization of information on effectiveness in relation to the individual patient leaves an evidence gap for clinicians.* [Italics added.]

Dr. Alan Feinstein, from the Department of Medicine at Yale University, echoes similar reservations in his article, “Problems in the evidence of evidence-based medicine.”²²⁵ Larry Culpepper and Thomas Gilbert, in their Lancet commentary, “Evidence and ethics,” focus on this same difficulty in the primary-care arena.²²⁶ Although the debate has continued over the past decade, these reasoned arguments have been heard less frequently as the push toward EBM has gained momentum. However, the problems described above have not been solved. Rather, with the advent of personalized medicine and systems biology, it is even more clear that the reductionist simplicity of the RCT frequently does not work to address the significant questions now facing 21st century practitioners in their struggle to cope with the epidemic of complex, chronic disease.^{227, 228, 229, 230, 231}

We can now begin to understand why the effect of research findings on clinical practice has been weaker than the early proponents of EBM postulated. The first problem that has impeded the successful application of EBM to patient care is the complex nature of the translation of research studies to the individual patient’s unique clinical problem(s)—what Larry Weed called knowledge coupling.^{232, 233}

John Hampton, Professor of Cardiology, University Hospital, Nottingham, England, in a review titled “Evidence-based medicine, opinion-based medicine, and real-world medicine,” reasons: “*Clinical trials will tell us what treatments are effective, but not necessarily which patients should receive them... Treatment must always be tailored to the individual patient.*”²³⁴ (We would add to that statement that RCTs can only tell us what treatments are effective *from among those studied*. The decision about what to investigate introduces so much bias into the evidence base that it would be difficult to overstate its impact.)

Added to this methodological conundrum are the real-world exigencies of daily clinical practice that make it virtually impossible to acquire, collate, and filter all relevant evidence prior to direct application to the unique needs of the patient. Imagine a clinic where, after each therapeutic encounter—involving both appropriate history taking and physical examination procedures—a problem list is developed and then carefully subjected to a medical literature search and analysis. The pace of clinical practice will not tolerate the inertia of such a process,²³⁵ even to improve the care of patients who may be in desperate need of new interventions based on emerging evidence.

A second major issue is even more complex. If medical care were as simple as making a diagnosis and then prescribing an appropriate pharmacologic agent (or agents), then the EBM system, as presently configured and applied, might work—but only if appropriate *Problem Oriented Evidence that Matters* (POEMs)^{xiii, 236} were available for each medical problem (and disregarding, for the moment, that

^{xiii}To assist the practicing physician’s effective inclusion of new evidence into daily practice, both government-sponsored and commercially affiliated organizations have moved EBM forward with a collation of filtered studies called: *Problem Oriented Evidence that Matters* (POEMs). Most POEMs and most studies in the Cochrane Collection are research trials of pharmacologic therapeutic interventions. It is now possible to search these specific databases, or self-developed relevant databases that review groups of studies that directly link research findings with specific clinical problems.

most chronic disease is complicated by multiple comorbidities that are rarely addressed by POEMs). Unfortunately, the “better living through chemistry” dream that fueled half a century of research has not, in fact, created a healthier population (see Chapter 2).²³⁷ Although many acute medical problems do appear to respond consistently as envisioned by the EBM model, more than 70% of health problems presenting to clinicians today are both chronic and complex²³⁸ (Chapter 2), and they require a different approach. “Treating only known biological components of disease minimizes the ability of the practitioner to tailor therapeutic interventions to individual patients.”²³⁹

Despite these sobering facts, physician education, training, and reimbursement, as well as research designs for clinical studies that physicians depend upon for effective decision making, continue to be focused primarily on an acute-care model that emphasizes pharmacologic solutions for complex, chronic problems, leaving the discerning clinician without the evidence and tools needed for addressing their patients’ complex needs.

It’s not enough, of course, for us to understand what’s wrong. We must also seek better solutions for these urgent problems, regardless of the difficulty of the task and the elusiveness of the answers. The RCT tool was developed during a specific period in our medical history and worked well to differentiate the traditionalists, who claimed that clinical experience trumped bench science, from the scientists, who perceived the value in systematic inquiry. Major strides in treatment have occurred in the intervening 50 to 60 years as a result of the shift toward the use of RCT methodology. But we are now at another nodal decision point, unique to our cultural and medical evolution. We need more sophisticated tools to shed light on the nature of the web-like interweaving of mechanisms at work in complex, chronic illness.^{240, 241, 242} While alternate study designs and statistical methodologies are being developed for analyzing complex data sets,^{243, 244, 245} we must return the practice of EBM to its original mission of using evidence to inform clinical experience and to expand the understanding of basic mechanisms of health and disease.^{246, 247} This will help to reverse the decade-long plunge toward “... reducing clinical practice to the technical implementation of research findings.”^{248, 249}

In sum, we are now facing another major transition in how we perceive and utilize evidence in clinical medicine. Thomas Kuhn offers this insightful analysis:

When defects in an existing paradigm accumulate to the extent that the paradigm is no longer tenable, the paradigm is challenged and replaced by a new way of looking at the world. Medical practice is changing, and the change, which involves using the medical literature more effectively in guiding medical practice, is profound enough that it can appropriately be called a paradigm shift.²⁵⁰

A Science-Using Profession

Given the serious limitations of applying the EBM model in clinical practice, we must ask two questions central to the future of medicine:

- ⊗ How do we develop an effective therapeutic relationship based upon (1) efficacious, reproducible, and personalized clinical applications that are solidly anchored in science, (2) emerging knowledge about the multifactorial causes of chronic disease, and (3) an expanded awareness of the nature of clinical/critical thinking?

- ⊗ How do we transition from an EBM-based, guideline-driven, prescriptive clinical practice to an individualized, patient-centered approach that captures both the science and the art of medicine?

First, we must recognize that most clinicians, by professional training and inclination, are not scientists.

Clinical medicine is a science-using profession. It is true that diagnosis and treatment have become intensely science-using activities, but these activities have a distinctly different process and endpoint than those of the professional scientist.²⁵¹ “Physicians start from the demands of the patient’s condition and not from the demand for generalizable knowledge, and their goal is just as particular: to treat the patient’s illness, not to test the therapy.”²⁵² The evidence needs of clinical medicine are also distinctly different. The focus on application and usefulness centers on how the evidence informs the assessment and treatment process for each individual patient, given that patient’s unique genetic propensities and unique environmental influences.

At a number of points in this paper, we have documented how most clinical evidence based on RCTs informs about cohorts of patients with similar signs and symptoms (the basis of diagnosis and diagnostic groups), but not does not necessarily provide decision support for an individual patient. The primary responsibility of the attending clinician is to ferret out meaningful evidence for each patient, knowing that unique genomic specificities may predispose that patient to unanticipated results. From this perspective, evidence often serves to qualify *insight*, but when applied in a simplistic or statistically linear way, can create unintended mischief.²⁵³ From this perspective, every maneuver, either further assessment or therapeutic intervention, becomes a clinical probe that must be assessed in partnership with the client as the shared journey of investigation and healing proceeds.

Dr. Sackett, founder and advocate for EBM, was quite clear about this in the early development of EBM: “Evidence based medicine is the conscientious, explicit, and judicious use of current best evidence in making decisions about the care of individual patients. The practice of evidence based medicine means integrating individual clinical expertise with the best available external clinical evidence from systematic research.... *Good doctors use both individual clinical expertise and the best available external evidence and neither alone is enough.*”²⁵⁴ [Italics added.]

The combining of these elements can be viewed as a Venn diagram, where the best outcomes occur when all three elements are represented (Figure 9).

Figure 9:
Optimal Outcomes: Applying Evidence-based Medicine to the Real World

Another Perspective on the Biomedical Model

The complexity of the developing explanatory models has been serially addressed in the *Annals of Family Medicine*, a peer-reviewed medical journal “dedicated to advancing knowledge essential to understanding and improving health and primary care,” including the development of methodology and theory for addressing this conundrum. In the article, “The biopsychosocial model 25 years later: Principles, practice, and scientific inquiry,”²⁵⁵ the authors critique the limitations of the conventional biomedical model and the research methodologies that evolve from this model and preview the evolving model of complexity and causality and the nested model of structural causality:

Few morbid conditions could be interpreted as being of the nature “one microbe, one illness”; rather, there are usually multiple interacting causes and contributing factors. Thus, obesity leads to both diabetes and arthritis; both obesity and arthritis limit exercise capacity, adversely affecting blood pressure and cholesterol levels; and all of the above, except perhaps arthritis, contribute to both stroke and coronary artery disease. Some effects (depression after a heart attack or stroke) can then become causal (greater likelihood of a second similar event). . . . These observations set the stage for models of circular causality that describe how a series of feedback loops sustain a specific pattern of behavior over time.^{256, 257, 258} Complexity science is an attempt to understand these complex recursive and emergent properties of systems^{259, 260} and to find interrelated proximal causes that might be changed with the right set of interventions.²⁶¹

David Deutsch, in *The Fabric of Reality*, describes the need for a next step in using the science of underlying pathophysiological mechanisms of disease in the clinical setting of medicine:

The science of medicine is perhaps the most frequently cited case of increasing specialization seeming to follow inevitably from increasing knowledge, as new cures and better treatments for more diseases are discovered. But as medical and biochemical research comes up with deeper explanations of disease processes (and healthy processes) in the body, understanding is also on the increase. More general concepts are replacing more specific ones as common, underlying molecular mechanisms are found for dissimilar diseases in different parts of the body. Once a disease can be understood as fitting into a general framework, the role of the specialist diminishes. . . . Physicians. . . can look up such facts as are known. But [more importantly] they may be able to apply a general theory to work out the required treatment, and expect it to be effective even if it has never been used before.²⁶²

The real question now facing every discerning, informed clinician²⁶³ is how to bring relevant, graded, emerging scientific evidence to the complex list of problems made unique by the patient’s genetic susceptibilities and potentialities that, in turn, communicate constantly with the ever-changing environment within which the patient lives. No RCT can inform, *in a specific way*, the appropriate clinical roadmap for assessment and planning for therapeutic interventions in this complex environment.²⁶⁴ Clinicians must use science; it is a powerful tool. But they should be in charge of how and when to use it, not dominated and intimidated by it.

The Heuristics that Guide Doctors' Thinking

We believe it is fair to say that the fear of uncertainty has led us to narrow our field of vision far too soon. “Science has not one method, but many. These include observation in the natural world, experimentation in the laboratory, mathematical proof, computer simulation with real data, analysis of surveys and demographical statistics, and thought experiments for the great geniuses, such as Galileo and Einstein. In the social sciences, a climate of anxious identification with a sub-discipline goes hand in hand with methodological rituals ... methodological uniformity and discipline-oriented research are two sides of the same coin....” A shift is needed to “free us from the straightjacket of methodological rituals, allowing us to consider and choose proper methodologies for the problem at hand and to verify a result obtained with one method by using other methods.”²⁶⁵

Has broad-based and open-minded scientific inquiry been skewed by EBM and its hierarchy of evidence codification and ranking?^{266, 267, 268, 269, 270, 271} Is the hegemony of EBM in contemporary medicine, as exemplified by Drs. Montori and Guyatt,²⁷² closing the door on the reintegration of the science and art of medicine?^{xiv} We need to ask what we have surrendered by de-emphasizing “unsystematic clinical experience and pathophysiologic rationale.” What is the irreplaceable loss in patient outcomes with the dismissing of experience, intuition, and wisdom? What must we do to develop skills and methodologies appropriate to clinical decision making in a context of uncertainty?

There is a robust literature that explores the actual methodologies used by clinicians who must make decisions when time and information are limited and the outcome is uncertain. It is clear from brain research that there is an important difference between the human brain and other features of the universe. The brain is a complicated, nonlinear, living system capable of self-organization. The brain does not respond to incoming stimuli in a direct, reflex-like action but continuously changes, constructing its own neural activity patterns in order to adapt to and synchronize with external stimuli. Genetic makeup and continuous stimuli from the environment are the only factors that create individual differences; the twin magnets of chaos and self-organization shape the constant interplay of those factors. The human mind is highly capable of dual processing; in fact, the continuous and virtually seamless integration of reason to test intuition and of intuition to generate the creative thinking that fuels rational inquiry is what advances insight and knowledge.

We usually represent problems in a linear fashion despite the convincing evidence that this type of modeling is not appropriate or adequate for studying the nervous system or human behavior.^{273, 274} This naturally leads to some interesting conclusions about the interrelationship of brain and mind when faced with decision making in a sea of uncertainty.^{275, 276, 277, 278, 279} The mind is an adaptive toolbox with genetically, culturally, and individually created and transmitted rules of thumb. These rules of thumb are called heuristics and are foundational to daily function, intuition, or inspiration.²⁸⁰ *The study of judgment under uncertainty is the study of heuristics.* The human species' response to uncertainty is to rely upon experience, coupled with knowledge, data, and applied wisdom through processes such as heuristics and insight.

^{xiv}In their 2008 review of the progress in EBM, VM Montori and GH Guyatt reiterate a basic principle of EBM cited earlier in this chapter: “Evidence-based medicine *de-emphasizes intuition, unsystematic clinical experience, and pathophysiologic rationale* (italics added) as sufficient grounds for clinical decision making and stresses the examination of evidence from clinical research,” ignoring the significant push back from the international scientific and clinical community regarding the hobbling effects of EBM on both research and translational medicine.

Heuristics and “rules of thumb” are synonymous terms. It is important to distinguish between heuristic and analytic thinking. For instance, heuristic thinking is indispensable for discovering a mathematical proof, whereas analytic thinking is necessary for checking the steps of the proof.²⁸¹ A limited number of simplifying heuristics rather than more formal and extensive algorithmic processing is the rule.²⁸² The classic example of a heuristic that most people have experienced is the “rule of thumb” (gaze heuristic) used for catching a ball, as illustrated in Figure 10.

Figure 10:

How to Catch a Fly Ball: Players rely on unconscious rules of thumb. When a ball comes in high, a player fixates his gaze on the ball, starts running, and adjusts his speed so that the angle of the gaze remains constant.

From page 22 of the essay *Rationality for Mortals*, originally published in *Blackwell Handbook of Judgement and Decision Making*. Copyright Oxford University Press/UK Blackwell, 2004.

The angle of gaze is the angle between the eye and the ball, relative to the ground. For years, brain scientists assumed that a complex process of computations was required for tasks like catching a ball. The artificial intelligence (AI) groups attempted to duplicate these tasks with robotic technologies. However, research by the ‘heuristics’ groups showed a very different process at work.²⁸³ It turns out that a player who uses the *gaze* rule does not need to measure wind, air resistance, spin, or the other complex, causal variables. “All the relevant facts are contained in one variable: the angle of gaze. Note that a player using the *gaze heuristic* is not able to compute the point at which the ball will land. Yet the heuristic leads the player to the landing point...most fielders are blithely unaware of the gaze heuristic, despite its simplicity. Once the rationale underlying an intuitive feeling is made conscious, however, it can be taught.”²⁸⁴

Elwyn et al., in their well reasoned paper, “Decision analysis in patient care,”²⁸⁵ demonstrate the efficacy and comprehensiveness of this methodology. Naylor summarizes in his editorial comments on their paper (published in the *Lancet*):

The process of individualized decision analysis might best be viewed as a way of enhancing communication with patients, rather than as a “black box” from which directives emerge. But if that is the ultimate aim, it seems more useful to develop simple decision aids aimed at helping patients and doctors share information and work through tough choices in the clinical setting. To that end, Elwyn and colleagues call on clinicians and patients to communicate better while embracing fast and frugal rules of thumb [heuristics]. In so doing they have arguably drawn their

readers full circle—from *clinical art to bedside science and back again*. It is ironic, moreover, that the best lessons in *fast and frugal rules of thumb* may well come from understanding the cognitive processes of those master clinicians who consistently make superb decisions without obvious recourse to the canon of evidence-based medicine.²⁸⁶ [Italics added.]

If we are to develop both a clinical methodology and a curriculum that will approximate the best characteristics of successful clinicians, we must compare what is usually done with what could be done. A very pertinent example of how we might transform medical care affects the primary heuristic of contemporary medicine—the patient history and physical exam reporting structure (the H&P heuristic)—that dominates all communication among healthcare practitioners today. We will then compare it to the new heuristic developed by IFM to achieve a more comprehensive communication tool.

Every healthcare provider recognizes this formal construct for medical information and communication. It both describes and dictates the process of the patient visit. The story that emerges from a clinical encounter is typically organized around the following elements:

From Patient Encounter to the Diagnosis: The Conventional Medical Heuristic

- **Chief Complaint (CC)***
- **History of Present Illness (HPI)***
- **Past Medical History (PMH)***
- **Review of Organ Systems (ROS)***
- **Medication and Supplement History***
- **Dietary History***
- **Social, Lifestyle, Exercise History****
- **Physical Examination (PE)***
- **Laboratory and Imaging Evaluations***
- **Assessment and Diagnosis***
- **Treatment Interventions (usually pharmaceutical and/or procedure -based)***

*** = STANDARD PRACTICE**

**** = EXPANDED MODEL**

It is not always recognized that this construct facilitates the “fast and frugal processing” needed to efficiently collect, collate, and use patient information. The conventional H&P heuristic propels all information headlong toward the diagnosis, with the intention of identifying and prescribing the pharmaceutical or procedural therapy associated with that diagnosis. Each individual diagnosis is viewed as a distinct entity unto itself—often investigated during separate office calls and/or by different practitioners. There is no place in the conventional H&P heuristic to tie together multiple diagnoses into a consistent and coherent patient narrative. There is no identification of the antecedent conditions that may predispose the patient to the triggering of dysfunctional adaptive responses, nor of the mediators that may perpetuate the dysfunction. Thus, patients filtered through this conventional heuristic never have a chance

to be fully heard and understood in the context of their whole life experience. Instead, their stories are reduced to a series of diagnoses, treated by different specialists, often in isolation from one another.

The H&P heuristic was shaped by, and thus reinforces, the organ-system model of disease, with its distinct and separate information silos, rather than a systems-medicine perspective that encourages the search for common underlying mechanisms of, and pathways to, disease.

IFM's functional medicine heuristic (FM heuristic) expands upon the same basic structure we are all familiar with, but organizes the information to integrate the patient's genetic and developmental susceptibilities (*antecedents*), historical *triggers*, and ongoing *mediators* of disease. Thus, the patient's story emerges with greater detail, a broader context, and a different focus and ultimate goal:

The Functional Medicine Heuristic

- **Chief Complaint (CC)**
- **History of Present Illness (HPI)**
- **Past Medical History (PMH)**
 - Explore antecedents, triggers, and mediators of CC, HPI, and PMH
- **Review of Organ Systems (ROS)**
 - Genetic predispositions?
- **Medication and Supplement History**
- **Dietary History**
- **Social, Lifestyle, Exercise History**
- **Physical Examination (PE)**
- **Laboratory and Imaging Evaluations:**
 - Immune/inflammatory imbalance
 - Energy imbalance/mitochondrial dysfunction
 - Digestive/absorptive and microbiological imbalance
 - Detoxification/biotransformation/excretory imbalance
 - Imbalance in structural, boundary, and membrane integrity
 - Hormonal and neurotransmitter imbalances
 - Imbalance in mind - body - spirit integration
- **Initial Assessment:**
 - Enter data on Matrix form; look for common themes
 - Review underlying mechanisms of disease
 - Recapitulate patient's story
 - Organ system-based diagnosis
 - Functional medicine assessment: underlying mechanisms of disease; genetic and environmental influences
- **Treatment Plan:**
 - Individualized
 - Dietary, lifestyle, environmental
 - Nutritional, botanical, psychosocial, energetic, spiritual
 - May include pharmaceuticals and/or procedures

As can be seen in the FM heuristic, the diagnosis is one factor among many that help the clinician and patient explore why and how a condition was triggered and why and how the dysfunction is being mediated. From a disciplined filtering of the patient information through the Functional Medicine Matrix Model (see Chapter 5), patterns emerge that illuminate both the underlying causes of dysfunction as well as plausible (and multiple) points of leverage where individualized treatment can create improved function. The potential interventions reflect a broader array of health vectors than just pharmaceutical and procedural interventions because the FM heuristic elicits a pattern that helps the clinician and patient identify where lifestyle and environmental interventions can be applied.

Because clinical reasoning is very often grounded in heuristics (simplified models that guide evaluation and treatment at an unconscious level of awareness), we argue that to change the outcome, we must change the model. The ability to utilize heuristics when time and information are limited and outcomes are uncertain is a very special cognitive trait—an evolutionary breakthrough in adaptive cognition. To understand and refine clinical reasoning and clinical practice—to ultimately improve outcomes—a deeper understanding of these adaptive skills must be understood and consciously applied.

Insight

If we are to develop an effective model for the healing partnership, we must also explore the research that illuminates the emergence of insight as a reproducible phenomenon.^{xv} Brain research has illuminated very different functions of the left and right brain that explicate the objective neural correlates of a brain that produces insight. Among the most important features of this emerging view of brain function are the following:

- ⊕ Solving computational questions is primarily a left-brain function. Asking a computational question triggers left-brain activity at the expense of right-brain function. (This has tremendous relevance to the interactions between doctor and patient. When a patient is interrupted with a computational question in the midst of an attempt to describe a pattern of dysfunction, the patient's own opportunity for insight may be lost.)
- ⊕ If the left hemisphere excels at denotation—storing the primary meaning of a word—the right hemisphere deals with connotation, everything that gets left out of a dictionary definition, such as the emotional charge in a sentence or a metaphor. Language is so complex that the brain has to process it in two different ways at the same time. As humans, we need to see both the forest and the trees. The right hemisphere is what helps you see the forest.^{287, 288}
- ⊕ Much of the research into the adaptive unconscious (aka unconscious cognition) suggests that pattern recognition capacity resides in the right brain, but is not specifically localized.^{289, 290} Solving questions requiring insight generates activity that starts in the prefrontal cortex and eventually extends throughout the cortex and deeper structures,

^{xv}“What is insight? The term ‘insight’ is used to designate the clear and sudden understanding of how to solve a problem. Insight is thought to arise when a solver breaks free of unwarranted assumptions, or forms novel, task-related connections between existing concepts or skills.” (Bowden EM. New approaches to demystifying insight. *TRENDS in Cognitive Sciences*. 2005;9(7):322-28.)

searching for possible experiential information that contributes to the emergence of a pattern. It is the appearance of that pattern that sparks the “aha” or “Eureka!” experience in the connotative language centers of the right brain.

In brief, left-brain function helps us with the denotative, computational, linear functions of life and thought, whereas the right brain provides the connotative shadings that give depth and character and color to meaning. Right-brain function is the source of pattern recognition and moments of insight.

The researchers in this field have produced a robust and credible body of research about pattern recognition from experiments that delineate and substantiate the functions of unconscious cognition (the adaptive unconscious) that shape moments and expressions of insight.^{291, 292, 293} Reproducible patterns of brain activity correlate with the experience of insight.²⁹⁴ The prefrontal cortex does not simply function as an aggregator of information. Instead, like the conductor of an orchestra, brain wave activity and energy expenditure are coordinated as if instructed by the prefrontal cortex maestro, waving its baton and directing the players.

This is known as top-down processing, since the prefrontal cortex (the top of the brain) is directly modulating the activity of other areas. Studies show that cells in the right hemisphere are more broadly tuned than cells in the left hemisphere, with longer branches and more dendritic spines. As a consequence, neurons in the right hemisphere are collecting information from a larger area of cortical space. They are less precise but better connected. When the brain is searching for an insight, these are the cells that are most likely to produce it. A small fold of tissue on the surface of the right hemisphere, the anterior superior temporal gyrus (aSTG), becomes unusually active in the second before the insight. The activation is described as sudden and intense, a surge of electricity leading to a rush of blood.^{295, 296}

One of the unusual aspects of insight is not the revelation itself but what happens afterward. The adult brain is an infinite library of associations, a cacophony of competing ideas, and yet, as soon as the right association appears, we *know*. The new thought, which is represented by that rush of gamma waves in the right hemisphere, immediately grabs our attention. As soon as the insight happens, it seems so obvious. People can't believe they didn't see it before.^{297, 298, 299}

Insight researchers call the “aha” experience the *moment of categorical insight*. This moment of epiphany registers as a new pattern of neural activity in the prefrontal cortex. The brain cells have been altered by the breakthrough. An insight is a restructuring of information—it's seeing the same old thing in a completely new way. Once that restructuring occurs, you never go back.³⁰⁰

Insight and the Healing Partnership

“While it's commonly assumed that the best way to solve a difficult problem is to focus, minimize distractions, and pay attention only to the relevant details, this clenched state of mind may inhibit the sort of creative connections that lead to sudden breakthroughs. We suppress the very type of brain activity that we should be encouraging. Jonathan Schooler has recently demonstrated that making people focus on the details of a visual scene, as opposed to the big picture, can significantly disrupt the insight process. ‘It doesn't take much to shift the brain into left-hemisphere mode,’ he said.”³⁰¹ We can extrapolate that, as clinicians, although we don't ignore evidence, when we want insight about a patient's condition, we are clearly better off not turning to left-brain analysis of the most recent RCTs. And, when we want the patient's insight, we must learn to elicit the patient's story (pattern) and really listen to it.

Research focused on the typical, clinical therapeutic encounter has noted that clinicians interrupt the patient's flow of conversation within the first 12 to 18 seconds (or less) of the patient's response to a question.^{302, 303} This reproducible phenomenon in the conventional clinical setting makes sense if you compare the heuristic for contemporary medicine to the functional medicine heuristic. The heuristic of conventional medicine (rule of thumb) achieves the stated goal in an expeditious manner: clinicians use it to identify the primary organ system domain of the presenting problem and then focus on the differential diagnosis within that domain, marching resolutely to the final diagnosis. This is a computational process, without need for a partnership that can produce insight into the underlying causes and mechanisms of the medical problem.

The functional medicine heuristic, on the other hand, requires a carefully nurtured and protected partnership between the clinician and the patient to illuminate the underlying mechanisms of the patient's illness(es). The FM heuristic requires an iterative, cooperative process that yields a more complete narrative story. From a thorough investigation of the antecedents, triggers and mediators of the patient's condition, emerge information and insights that can help to shape a deeper and more comprehensive therapeutic response.

Summary

We have devoted this chapter to achieving a better understanding of an urgent problem facing clinicians today: how to combine both science and art, evidence and insight, into an individualized, patient-centered approach to complex, chronic disease. We do not claim to have *the* (sole or definitive) answer. But we do offer a new focus for both education and practice that can be described and substantiated, taught and practiced. We have presented findings that suggest that the management of uncertainty—the inherent context of clinical medicine—requires a change in the therapeutic relationship on the part of both clinician and patient and a change in how we view and use evidence. The technical therapeutic encounter that has characterized a great deal of patient care for the last few decades must be transformed into a healing partnership through appropriate applications of scientific understanding, evidence from clinical trials, and a new understanding of brain function.

The Institute for Functional Medicine's model of comprehensive care and primary prevention for complex, chronic illnesses (described further in Chapter 5) is grounded in both science (the Functional Medicine Matrix Model; evidence about common underlying mechanisms and pathways of disease; evidence about effective approaches to the environmental and lifestyle sources of disease) and art (the healing partnership and the search for insight in the therapeutic encounter). These two cornerstones of clinical medicine must be integrated into our teaching and practice in order to achieve what we owe to our patients and ourselves—a more effective response to the epidemic of chronic disease. We assert that this can be done.

Chapter 5

FUNCTIONAL MEDICINE: A 21ST CENTURY MODEL OF PATIENT CARE AND MEDICAL EDUCATION

It is much more important to know what sort of a patient has a disease than what sort of a disease a patient has. The good physician treats the disease; the great physician treats the patient who has the disease.

—WILLIAM OSLER

Treat the patient, not the diagnosis.

—THE INSTITUTE FOR FUNCTIONAL MEDICINE

In this chapter, we will review the basic principles, constructs, and methodology of functional medicine. It is not the purpose of this paper to recapitulate the range and depth and science of functional medicine; books and monographs covering that material in great detail are already available for the interested clinician and for use in health professions schools. Our purpose in the first part of this chapter is to describe how functional medicine is organized to deliver personalized, systems medicine and, as such, is equipped to respond to the challenge of treating complex, chronic disease more effectively. In the second part of the chapter, we will discuss how clinicians can be helped to re-integrate the art and science of medicine to create a healing partnership.

Part I: What is Functional Medicine?

Functional medicine conceptualizes health and illness as part of a continuum in which all components of the human biological system interact dynamically with the environment. These interactions produce patterns that change over time in individuals. To manage the complexity inherent in this approach, functional medicine has adopted practical models for obtaining and evaluating clinical information that leads to individualized, patient-centered therapies.

Functional medicine encompasses a dynamic approach to assessing, preventing, and treating complex, chronic disease. It helps clinicians identify and ameliorate dysfunctions in the physiology and biochemistry of the human body as a primary method of improving patient health. In this model of practice, we emphasize that chronic disease is almost always preceded by a period of declining function in one or more of the body's systems. Returning patients to health requires reversing (or substantially improving) the specific dysfunctions that have contributed to the disease state. Those dysfunctions are, for each of us, the result of lifelong interactions among our environment, our lifestyle, and our genetic predispositions. Each patient, therefore, represents a unique, complex, and interwoven set of influences on intrinsic functionality that have set the stage for the development of disease or the maintenance of health.

Historically, the word “functional” has been used somewhat pejoratively in medicine. It has implied a disability associated with either a geriatric or psychiatric problem. We suggest, however, that this is a very limited definition of an extremely useful word. Medicine has not really produced an efficient method for identifying and assessing changes in basic physiological processes that produce symptoms of increasing duration, intensity, and frequency, even though we know that such alterations in function often represent the first signs of conditions that, at a later stage, become pathophysiologically definable diseases. If we broaden the use of functional to encompass this view, *functional medicine* becomes the science and art of detecting and reversing alterations in function that clearly move a patient toward chronic disease over the course of a lifetime. Thus, with functional medicine, we begin to define a model of patient care that seeks to identify underlying chronic dysfunctions associated with altered physiological processes and to maximize functionality at all levels of body, mind, and spirit.

One way to conceptualize where functional medicine falls in the continuum of health and health care is to examine the functional medicine “tree.” In its approach to complex, chronic disease, functional medicine encompasses the whole domain represented by the graphic shown in Figure 11, but *first* addresses the patient's core clinical imbalances, fundamental physiological processes, environmental inputs, and genetic predispositions. Diagnosis, of course, is part of the functional medicine model, but the emphasis is on understanding and improving the functional core of the human being as the starting point for intervention.

Figure 11:
The Continuum of Health and Health Care

Functional medicine clinicians focus on restoring balance to the dysfunctional systems by strengthening the fundamental physiological processes that underlie them, and by adjusting the environmental and lifestyle inputs that nurture or impair them. This approach leads to therapies that focus on restoring health and function, rather than simply controlling signs and symptoms.

Principles

Seven basic principles characterize the functional medicine paradigm:

- ⊕ Acknowledging the **biochemical individuality** of each human being, based on the concepts of genetic and environmental uniqueness
- ⊕ Incorporating a **patient-centered** rather than a disease-centered approach to treatment
- ⊕ Seeking a dynamic balance among the internal and external factors in a patient's body, mind, and spirit
- ⊕ Addressing the **web-like interconnections** of internal physiological factors
- ⊕ Identifying **health as a positive vitality**—not merely the absence of disease—and emphasizing those factors that encourage a vigorous physiology
- ⊕ **Promoting organ reserve** as a means of enhancing the health span, not just the life span, of each patient
- ⊕ Functional medicine is a **science-using profession**

Environmental Inputs

At the base of the medicine tree graphic are found the building blocks of life, as well as the primary influences on them. When we talk about influencing gene expression, we are interested in the interaction between environment in the broadest sense and any genetic predispositions with which a person may have been born—including the epi genome.^{xvi} Many environmental factors that affect genetic expression are (or appear to be) a matter of choice (such as diet and exercise); others are very difficult for the individual patient to alter or escape (air and water quality, toxic exposures); and still others may be the result of unavoidable accidents (trauma, exposure to harmful microorganisms in the food supply). Some factors that may appear modifiable are heavily influenced by the patient's economic status—if you are poor, for example, it may be impossible to choose more healthful food, decrease stress in the workplace and at home, or take the time to exercise and rest properly. Existing health status is also a powerful influence on the patient's ability to alter environmental input. If you have chronic pain, exercise may be extremely difficult; if you are depressed, self-activation is a huge challenge.

^{xvi}Epigenetics—the study of how environmental factors can affect gene expression without altering the actual DNA sequence, and how these changes can be inherited through generations.

The influence of these inputs on the human organism is indisputable and they are often powerful agents in the battle for health. Ignoring them in favor of the quick fix of writing a prescription means the cause of the underlying dysfunction may be obscured, but is usually not eliminated. In general terms, the environmental inputs listed below should be considered when working to reverse dysfunction or disease and restore health:

- ⊗ Diet (type and quantity of food, food preparation, calories, fats, proteins, carbohydrates)
- ⊗ Nutrients (both dietary and supplemental)
- ⊗ Air
- ⊗ Water
- ⊗ Microorganisms (and the general condition of the soil in which food is grown)
- ⊗ Physical exercise
- ⊗ Trauma
- ⊗ Psychosocial and spiritual factors (including family, work, community, economic status, stress, and belief systems)
- ⊗ Xenobiotics
- ⊗ Radiation

Fundamental Physiological Processes

There are certain physiological processes that are necessary to life. These are the “upstream” processes that can go awry and create “downstream” dysfunctions that eventually become disease entities. Functional medicine requires that clinicians consider these in evaluating patients, so that intervention can occur at the most fundamental level possible. They are:

1. Communication
 - outside the cell
 - inside the cell
2. Bioenergetics/Energy Transformation
3. Replication/Repair/Maintenance/Structural Integrity
4. Elimination of Waste
5. Protection/Defense
6. Transport/Circulation

Although these fundamental physiological processes are usually taught in the first two years of medical training, where they are appropriately presented as the foundation of modern, scientific patient care, subsequent training in the clinical sciences often fails to fully integrate knowledge of the functional mechanisms of disease with therapeutics and prevention, emphasizing instead teaching/learning based

on organ system diagnosis.³⁰⁴ Focusing predominantly on organ system diagnosis without examining the underlying physiology that produced the patient's signs, symptoms, and disease often leads to managing patient care by matching diagnosis to pharmacology. The job of the healthcare provider then becomes a technical exercise in finding the drug or procedure that best fits the diagnosis (not necessarily the patient), leading to a significant curtailment of critical thinking pathways: "Medicine, it seems, has little regard for a complete description of how a myriad of pathways result in any clinical state."³⁰⁵

Even more important, pharmacologic treatments are often prescribed without careful consideration of their physiological effects across all organ systems and physiological processes (and genetic variations).³⁰⁶ Pharmaceutical companies have exploited this weakness. Did you ever see a drug ad that urged the practitioner to carefully consider the impact of all other drugs being taken by the patient before prescribing a new one? The marketing of drugs to specific specialty niches, and the use of sound bite sales pitches that suggest discrete effects, skews healthcare thinking toward this narrow, linear logic, as notably exemplified by the COX-2 inhibitor drugs that were so wildly successful on their introduction, only to be subsequently withdrawn or substantially narrowed in use due to collateral damage.^{307, 308}

Core Clinical Imbalances

The functional medicine approach to assessment, both before and after diagnosis, charts a course using different navigational assumptions. Every health condition instigates a quest for information centered on understanding when and how the specific biological system(s) under examination spun out of control to begin manifesting dysfunction and/or disease. Analyzing all the elements of the patient's story, the signs and symptoms, and the laboratory assessment through a matrix focused on functionality requires analytic thinking and a willingness on the part of the clinician to reflect deeply on underlying biochemistry and physiology. The foundational principles of how the human organism functions—and how its systems communicate and interact—are essential to the process of linking ideas about multifactorial causation with the perceptible effects we call disease or dysfunction.

To assist clinicians in this process, functional medicine has adapted and organized a set of core clinical imbalances that function as the intellectual bridge between the rich basic science literature concerning physiological mechanisms of disease (first two years of medical training) and the clinical studies, clinical experience, and clinical diagnoses of the second two years of medical training. The core clinical imbalances serve to marry the mechanisms of disease with the manifestations and diagnoses of disease. Many common underlying pathways of disease are reflected in a few basic clinical imbalances:

- ⊕ Immune/inflammatory imbalance
- ⊕ Energy imbalance/mitochondrial dysfunction
- ⊕ Digestive/absorptive and microbiological imbalance
- ⊕ Detoxification/biotransformation/excretory imbalance
- ⊕ Imbalance in structural, boundary, and membrane integrity
- ⊕ Hormonal and neurotransmitter imbalances
- ⊕ Imbalance in mind-body-spirit integration

Using this construct, it becomes much clearer that one disease/condition may have multiple causes (i.e., multiple clinical imbalances), just as one fundamental imbalance may be at the root of many seemingly disparate conditions (see Figure 12).

Figure 12:
Core Clinical Imbalances—Multiple Influences

The most important precept to remember about functional medicine is that restoring balance—in the patient’s environmental inputs and in the body’s fundamental physiological processes—is the key to restoring health.

Constructing the Model

Combining the principles, environmental inputs, fundamental physiological processes, and core clinical imbalances creates a new information-gathering-and-sorting architecture for clinical practice. This new model includes an explicit emphasis on principles and mechanisms that weld meaning and mechanistic explanations to the diagnosis and deepen the clinician’s understanding of the often overlapping ways things go wrong. Any methodology for constructing a coherent story and an effective therapeutic plan in the context of complex, chronic illness must be flexible and adaptive. Like an accordion file that can compress and expand upon demand, the amount and kind of data needed will necessarily change in accordance with the patient’s situation and the clinician’s time and ability to piece together the underlying threads of dysfunction. There are many pathways to illness; therefore, the accordion file must expand to incorporate a much larger database of relevant information. For example, the Chief Complaint, History of Present Illness, and Past Medical History sections must expand to include a thorough investigation of antecedents, triggers, and mediators. Personalized medical care without this expanded investigation will fall short.

Distilling the data from the expanded history, physical exam, and laboratory into a narrative story line that includes antecedents, triggers, and mediators can be challenging. Key to developing a thorough narrative

is organizing the story according to the seven common underlying mechanisms that influence health (the core clinical imbalances), as shown on the Functional Medicine Matrix Model™ form (see Figure 13).

Figure 13:
The Functional Medicine Matrix Model™ Form

The matrix form helps organize and prioritize information, and also clarifies the level of present understanding, thus illuminating where further investigation is needed. For example, indicators of inflammation on the matrix might lead the clinician to request tests for specific inflammatory markers (such as hsCRP, interleukin levels, and/or homocysteine). Essential fatty acid levels, methylation pathway abnormalities, and organic acid metabolites help determine adequacy of dietary and nutrient intakes. Markers of detoxification (glucuronidation and sulfation, cytochrome P450 enzyme heterogeneity) can determine functional capacity for molecular biotransformation. Neurotransmitters and their metabolites (vanilmandelate, homo vanillate, 5-hydroxyindoleacetate, quinolinate) and hormone cascades (gonadal and adrenal) have obvious utility in exploring messenger molecule balance. CT scans, MRIs, or plain x-rays extend our view of the patient's structural dysfunctions. The use of bone scans, DEXA scans, or bone resorption markers^{309, 310} can be useful in further exploring the web-like interactions of the matrix.

Newer, useful technologies such as functional MRIs, SPECT or PET scans offer more comprehensive assessment of metabolic function within organ systems. It is the process of completing a comprehensive history and physical and then charting these findings on the matrix that best directs the choice of laboratory work and successful treatment.

A completed matrix form facilitates the review of common pathways, mechanisms, and mediators of disease, and helps clinicians select points of leverage for treatment strategies. However, even with the matrix as an aid to synthesizing and prioritizing information, it can be very useful to consider the impact of each variable at five different levels:

1. Whole body (the “macro” level)
2. Organ system
3. Metabolic or cellular
4. Subcellular/mitochondrial
5. Subcellular/gene expression

Therapies should be chosen for their potential impact on the most central imbalances of the particular patient. Evaluating interventions that are available at each of the five levels can help to identify a reasonably comprehensive set of options from which to choose. The following lists incorporate only a few examples of various types of interventions within these five different levels.

1. **Whole body interventions:** Because the human organism is a complex adaptive system, with countless points of access, interventions at one level will affect points of activity in other areas as well. For example, improving the patient’s sleep will beneficially influence the immune response, melatonin levels, T cell lymphocyte levels, and will help to decrease oxidative stress. Exercise reduces stress, improves insulin sensitivity, and improves detoxification. Reducing stress (and/or improving stress management) can reduce cortisol levels, improve sleep, improve emotional well being, and reduce the risk of heart disease. Changing the diet can have myriad effects on health, from reducing inflammation to reversing coronary artery disease.
2. **Organ system interventions:** These interventions are used more frequently in the acute presentation of illness. Examples include splinting; draining lesions; repairing lacerations; reducing fractures, pneumothoraxes, hernias or obstructions; or removing a stone to re-establish whole organ function. There are many interventions that improve organ function. For example, bronchodilators improve air exchange, thereby decreasing hypoxia, reducing oxidative stress, and improving metabolic function and oxygenation in a patient with reactive airway disease.

3. **Metabolic or cellular interventions:** Cellular health can be addressed by insuring the adequacy of macronutrients, essential amino acids, vitamins, and cofactor minerals in the diet (or, if necessary, from supplementation). An individual's metabolic enzyme polymorphisms can profoundly affect his or her nutrient requirements. For example, adding conjugated linoleic acid (CLA) to the diet can alter the PPAR system, affect body weight, and modulate the inflammatory response.^{311, 312, 313} However, in a person who is diabetic or insulin resistant, adding CLA may induce hyperinsulinemia, which is detrimental.^{314, 315} Altering the types and proportions of carbohydrates in the diet may increase insulin sensitivity, reduce insulin secretion, and fundamentally alter metabolism in the insulin-resistant patient. Supporting liver detoxification pathways with supplemental glycine and N-acetylcysteine improves the endogenous production of adequate glutathione, an essential antioxidant in the central nervous system and GI tract.
4. **Subcellular/mitochondrial interventions:** There are many examples of mitochondrial nutrient support interventions.^{316, 317} Inadequate iron intake causes oxidants to leak from mitochondria, damaging mitochondrial function and mitochondrial DNA. Making sure there is sufficient iron helps alleviate this problem. Inadequate zinc intake (found in >10% of the U.S. population) causes oxidation and DNA damage in human cells.³¹⁸ Insuring the adequacy of antioxidants and cofactors for the at-risk individual must be considered in each part of the matrix. Carnitine, for example, is required as a carrier for the transport of fatty acids from the cytosol into the mitochondria, improving the efficiency of beta oxidation of fatty acids and resultant ATP production. In patients who have lost significant weight, carnitine undernutrition can result in fatty acids undergoing omega oxidation, a far less efficient form of metabolism.³¹⁹ Patients with low carnitine may also respond to riboflavin supplementation.³²⁰
5. **Subcellular/gene expression interventions:** Many compounds interact at the gene level to alter cellular response, thereby affecting health and healing. Any intervention that alters NFκB entering the nucleus, binding to DNA, and activating genes that encode inflammatory modulators such as IL-6 (and thus CRP), cyclooxygenase 2, IL-1, lipoxigenase, inducible nitric oxide synthase, TNF-α, or a number of adhesion molecules will impact many disease conditions.^{321, 322} There are many ways to alter the environmental triggers for NFκB, including lowering oxidative stress, altering emotional stress, and consuming adequate phytonutrients, antioxidants, alpha-lipoic acid, EPA, DHA, and GLA.³²³ Adequate vitamin A allows the appropriate interaction of vitamin A-retinoic acid with over 370 genes.³²⁴ Vitamin D in its most active form intercalates with a retinol protein and the DNA exon and modulates many aspects of metabolism including cell division in both healthy and cancerous breast, colon, prostate, and skin tissue.³²⁵ Vitamin D has key roles in controlling inflammation, calcium homeostasis, bone metabolism, cardiovascular and endocrine physiology, and healing.³²⁶

Experience using this model, along with improved pattern-recognition skills, will often lessen the need for extensive laboratory assessments. There will always be, however, certain clinical conundrums that simply cannot be assessed without objective data and, for most patients, there may be an irreducible minimum of laboratory assessments required to accumulate information. For example, in the clinical workup of autistic spectrum disorders in children, heavy metal exposure and toxicity may play an important role. Heavy metal body burden cannot be sensibly assessed without laboratory studies. Another example is

in the context of the progressive, ongoing workup. When clinical acumen and educated steps in both assessments and therapeutic trials do not yield expected improvement, lab testing often provides rewarding information when focused on the unexpected outcomes in the progressive workup. This is frequently the context for focused genomic testing. In most initial workups, lab and imaging technologies can be reserved for those complex cases where the initial interventions prove insufficient to the task of functional explication.

Even using the functional medicine model that has been reviewed here, no single practitioner—and no single discipline—can cover all the viable therapeutic options. Interventions will differ by training, licensure, specialty focus, and even by beliefs and ethnic heritage. However, all healthcare disciplines (and all medical specialties) can—to the degree allowed by their training and licensure—use a functional medicine approach, including integrating the matrix as a basic template for organizing and coupling knowledge and data. So, functional medicine can provide a common language and a unified model to facilitate integrated care. Regardless of what discipline the primary care provider has been trained in, developing a network of capable, collaborative clinicians with whom to co-manage challenging patients and to whom referrals can be made for therapies outside the primary clinician's own expertise will enrich patient care and strengthen the clinician-patient relationship.

Part II: The Healing Partnership— A Synthesis of the Art and Science of Medical Practice

We form partnerships to achieve an objective. For example, a business partnership forms to engage in commercial transactions for financial gain; a marriage partnership forms to build a caring, supportive home-centered environment. A *healing partnership* forms to heal the patient through the integrated application of both the art of medicine (insight driven) and the science of medicine (evidence driven). An effective partnership requires that trust and rapport be established. Patients must feel comfortable telling their stories and revealing intimate information and significant events.

The characteristics of a *therapeutic encounter* are fundamentally different from a *healing partnership*, and each emerges from specific emphases in training. In the therapeutic encounter, the relationship forms to assess and treat a medical problem using (usually) an organ system structure, a differential diagnosis process, and a treatment toolbox focused on pharmacology and medical procedures. The therapeutic encounter pares down the information flow between physician and patient to the minimum needed to identify the organ system domain of most probable dysfunction, followed by a sorting system search (the *differential diagnosis heuristic*). The purpose of this relationship is to arrive at the most probable diagnosis as quickly as possible and select an intervention based on probable efficacy. The relationship is a left brain-guided conversation controlled by the clinician, steeped in Bayesian statistics (EBM), and characterized by algorithmic processing and statistical thinking.^{327, 328}

The functional medicine *healing partnership* forms with a related but broader purpose: to help the patient heal by identifying the underlying mechanisms and influences that initiated and continue to mediate the patient's illness(es). This type of relationship emphasizes a shared responsibility for both identifying the causes of the patient's condition and achieving insight about enduring solutions. The healing partnership is critical to the delivery of *personalized, systems medicine*, and to manage the uncertainty (choices under risk)

inherent in clinical practice. Here, in the healing partnership, we find the appropriate utilization and integration of left-brain and right-brain functions.

Germane to this discussion, Dr. Jerome Groopman—quoted previously in Chapter 4—states:

So a thinking doctor returns to language: “Tell me the story again as if I’d never heard it—what you felt, how it happened, when it happened.”³²⁹

In language, we have the fullest expression of the integration of left- and right-brain function. Language is so complex that the brain has to process it in different ways simultaneously—both denotatively and connotatively. For complexity and nuance to emerge in language, we need the left brain to see the trees, the right brain to help us see and understand the forest.^{330, 331}

To grasp the profound importance of the *healing partnership* to the creation of a system of medicine adequate to the demands of the 21st century, we need to briefly address the nature of healing and its role in the therapeutic relationship. We have noted an emerging body of research in this area.^{332, 333, 334} As Louise Acheson, MD, MS, Associate Editor for the *Annals of Family Practice*, articulated recently in that journal³³⁵:

It is challenging to research this ineffable process called healing.... Hsu and colleagues asked focus groups of nurses, physicians, medical assistants, and randomly selected patients to define healing and describe what facilitates or impedes it.³³⁶ The groups arrived at surprisingly convergent definitions: “Healing is a dynamic process of recovering from a trauma or illness by working toward realistic goals, restoring function, and regaining a personal sense of balance and peace.” They heard from diverse participants that “healing is a journey” and “relationships are essential to healing.”

In the 20th century, contemporary medicine, traditionally considered a healing profession, evolved away from the role of *healer of the sick* to that of *curing disease through modern science*. Research into this transition reveals that healing was/is associated with themes of wholeness, narrative, and spirituality. Professionals and patients alike report healing as an intensely personal, subjective experience involving a reconciliation of meaning for an individual and a perception of wholeness. The biomedical model as currently configured no longer encompasses these traditional characteristics for practitioners. Healing in a holistic sense has faded from medical attention and is rarely discussed in biomedical research reports. Contemporary medicine considers the wholeness of healing to be beyond its orthodoxy—the domain of the nonscientific and nonmedical.³³⁷

Research into the role of healing in the medical environment has recently generated some thoughtful and robust investigations. John Scott and his co-investigators’ research into the healing relationship found very similar descriptions to those of Hsu’s group, mentioned above. The participants in the study³³⁸ articulated aspects of the healing partnership as:

1. Valuing and creating a nonjudgmental emotional bond
2. Appreciating power and consciously managing clinician power in ways that would most benefit the patient
3. Abiding and displaying a commitment to caring for patients over time

Three relational outcomes result from these processes: trust, hope, and a sense of being known. Clinician competencies that facilitate these processes are self-confidence, emotional self-management, mindfulness, and knowledge.³³⁹ In this rich soil, the healing partnership flourishes.

The starting point for creating a healing partnership is the patient’s experience: *People, not diseases, can heal.* The integration of brain science research discussed in Chapter 4—to frame and apply right- and left-brain functions to create a *mindful, insightful* context—enhances the healing partnership during the therapeutic encounter. Mindful integration of brain function is at the heart of a healing partnership. Some of the basic steps for establishing a healing partnership include:

1. Allow patients to express, without interruption,^{xvii} their story about why they have come to see you. (This is an elaboration of the Chief Complaint and Present Illness.) The manner in which the patient frames the initial complaints often presages later insight into the root causes. Any interruption in this early stage of narrative moves the patient back into left-brain processing and away from insight.³⁴⁰
2. After focusing on the main complaint, encourage the patient’s narrative regarding their present illness(es). Clarifications can be elicited by further open-ended questioning (e.g., “tell me more about that”; “what else do you think might be going on?”). During this portion of the interview, there is a switching back and forth between right- and left-brain functions.
 - During this conversation, signs and symptoms of the present illness are distributed by the practitioner into the Functional Medicine Matrix Model form, according to the functional medicine heuristic sorting system described in Chapter 4.
 - The parsing is determined by an assessment of probable underlying causes—based on the robust research evidence base about common underlying mechanisms of disease—and ongoing mediators of the disease.
3. Next, convey to the patient in the simplest terms possible that to achieve lasting solutions to the problem(s) for which he/she has come seeking help, a few fundamental questions must be asked and answered in order to understand the problem in the context of the patient’s personal life. This framing of the interview process moves the endeavor from a left-brain compilation to a narrative that encourages insight—based on complex pattern recognition—about the root causes of the problem.
4. Explaining the structure of the next step helps the patient participate in a journey of exploration about their illness—and their search for health. At this stage, partial control is handed over to the patient with the statement: “*Without your help, we cannot understand your medical problem in the depth and breadth you deserve.*” Leo Galland, MD originally articulated the structure for the patient’s part of the investigation in his antecedents/triggers/mediators schema (ATM model).³⁴¹ (An excerpt from his outstanding chapter on this topic in the *Textbook of Functional Medicine* is included in the Appendix.)

^{xvii}Research focused on the therapeutic encounter has repeatedly found that clinicians interrupt the patient’s flow of conversation within the first 18 seconds or less, often denying the patient an opportunity to finish. (Beckman DB, et al. The effect of physician behavior on the collection of data. *Ann Intern Med.* 1984;101:692-96.)

- a) For determining **antecedent conditions**, the following questions are very useful:
 - When was the present problem not a problem? When were you free of this problem?
 - What were the circumstances surrounding the appearance of the problem?
 - Have similar problems appeared in family members?
- b) For **triggers**, the following question is critical:
 - What conditions, activities, or events seemed to initiate the problem? (Microbes and stressful personal events are examples, but illustrate quite different categories of triggers. Triggers by themselves are usually insufficient for disease formation, so triggers must be viewed within the context of the antecedent conditions.)
- c) **Mediators** of the problem are influences that help perpetuate it.
 - There can be specific mediators of diseases in the patient's activities, lifestyle, and environment. Many diverse factors can affect the host's response to stressors.
 - Any of the core clinical imbalances, discussed above and shown on the Functional Medicine Matrix Model, can transform what might have been a temporary change in homeostasis into a chronic allostatic condition.

It helps at this juncture to emphasize again that the following issues are elemental in forming a healing partnership:

- ⊗ Only the patient can inform the partnership about the conditions that provided the soil from which the problem(s) under examination emerge(s). The patient literally owns the keys to the joint deliberation that can provide insight about the process of achieving a healing outcome.
- ⊗ The professional brings experience, wisdom, tools, and techniques that can be applied to the journey of healing. The professional also works to create the context for a healing insight to emerge.
- ⊗ The patient's information, input, mindful pursuit of insight, and engagement become "the horse before the cart." The cart carries the clinician—the person who guides the journey using evidence, experience, and judgment, and who contributes the potential for expert insight.

The crux of the healing partnership is an equal investment of focus by both clinician and patient. They work together to identify the right places to apply leverage for change. Patients must commit to engage both their left-brain skills and their right-brain function to inform and guide the exploration to the next steps in assessment, therapy, understanding, and insight. Clinicians must also engage both the left-brain computational skills and the right-brain pattern-recognition functions that, when used together, can generate insight about the patient's story.

Two patient case studies (presented below by Dr. Jones) provide a glimpse into a functional medicine practice and the healing partnership that is necessary for success. The Appendix contains a form developed by IFM faculty for enhancing the pattern-recognition process in ulcerative colitis, and two additional cases with a comprehensive, detailed presentation of the use of the Matrix.

Patient #1: Kikuchi syndrome in an 18 year old female—insight from the healing partnership

Lila was an 18-year-old female transitioning from high school to college, who during the intervening summer experienced rapid onset of unexplained fever, profound fatigue, and lymphadenitis, especially pronounced in the cervical region. Her extended family included physicians, one who lived locally and led the initial investigation. The differential included lymphoma; because of the seriousness of this possible diagnosis, a biopsy of the enlarged cervical lymph nodes was completed expeditiously. Fortunately, the biopsy was more consistent with Kikuchi syndrome than lymphoma. The pathology of Kikuchi is a histiocytic necrotizing lymphadenitis. Her ANA was positive at 1:320, speckled. Kikuchi syndrome is presumed to be an immune response of T cells and histiocytes to an infectious agent, probably viral. At this point, I was asked to consult with the patient and her parents.

The patient was articulate, intelligent (she had been accepted to Harvard), and appeared recovered from the acute phase of her illness. Her father and mother were both present during the consultation. Lila was asked to narrate her story. During the telling of her story, I sorted her symptoms and signs using the FM Heuristic (Chapter 4) and the Functional Medicine Matrix Model (discussed above). At the end of recounting of her story, I explained to her and her parents the functional medicine sorting system, postulating that what we now knew from the history, lab results, and the biopsy was that Lila's immune system had probably been activated by a triggering agent (e.g., microbe, toxicant). I explained that our job now required forming a partnership, using Lila's and her parents' experiences through this episode of illness and my experience with immune-mediated illnesses to build a hypothetical story together.

I further explained that we would need to consider the conditions in Lila's family and "habits of living" history that could be antecedent to her illness. I explained that we would then move to the possible triggers in her recent past that might be causal or correlative in the acute expression of her illness. I explained that once an acceptable model emerged from our joint inquiry into the antecedents and triggers of her present illness, we would evaluate the possible probes that might elicit further information or generate treatment plans. They agreed to work together with me using this partnering model.

They were not aware of any exceptional family history of autoimmune or other immune dys-regulatory illnesses. The family's lifestyle, including eating and exercise habits, was laudable. We next addressed the issues of triggers. We knew from reading research sources on Kikuchi syndrome that the most common cause of the lymphadenitis associated with the syndrome was a microbe trigger. The parents were hopeful that we could perform lab analyses for a host of potential viral agents. Lila interrupted her parents at this point to advocate for quite a different possible cause.

Lila recounted that she had been seen in the regional dermatologic referral center for her worsening *acne vulgaris*. The treatment recommended by the consulting dermatologist was a sulfa-containing antibiotic. Before coming for consultation in my clinic, Lila had posited to her dermatologist and her primary care physician that her lymphadenitis was an adverse drug reaction. She and her parents had been told that the severity of her illness, if caused by a drug reaction, would necessarily be accompanied by a rash; she, however, was absent a rash. She had been advised to continue her antibiotic. Her parents retreated from this inquiry in the face of the authoritative disclaimer by both the specialist and the family doctor.

However, Lila did not retreat from her insight. We discussed her intuition (insight) and her reasoning. On the basis of her hypothesis, we jointly finalized a plan that included abstinence from her antibiotic. I advised against a planned back-packing trip to Mexico because of possible toxicant exposures in that environment that might confound her clinical story. We chose to call this a therapeutic probe with my added advice regarding follow-up. (We planned a low allergy diet and detoxification program IF the simple step of removing the triggering agent proved to be an insufficient intervention.)

That evening, I received an email from Lila with the following graph of her illness:

Outcome: Lila has been asymptomatic following continued abstinence from the sulfa-containing antibiotic. She has started her first semester at Harvard. The student health center physician became very interested in her story and has provided regular follow up, including lab. Her ANA titer has slowly returned to normal. No further interventions have been required. She has sought non-pharmacologic treatment interventions for her acne.

**Patient #2: Ulcerative Colitis in a 45 year old female—
providing a context for insight**

The next case illustrates the use of this same model: the pursuit of an antecedent and/or initial trigger for illness (these categories often overlap considerably)—that is, we looked for causes underneath the surface explanations for her condition. This 45-year-old female presented at my office for IBS and diverticulitis with a recent history of hemicolectomy for infectious colitis. The patient's primary residual postsurgical complaints were diffuse abdominal pain and loose stooling alternating with constipation. The review of her present illness revealed a history since her mid-twenties of "gut problems" (her words), including intermittent loose stools with alternating constipation. She had also over the years become intolerant of a plethora of foods. As a result, she had received thorough work-ups for food allergies and intolerances and was trying to follow a rather patchwork diet plan in response to these previous lab evaluations. She had received imaging and endoscopic procedures. However, she had not had follow-up colonoscopy since her surgery. We discussed the need to do follow-up endoscopy to evaluate her present symptoms (to rule out possible post-surgical adhesions complicating stool passage).

The conversation soon shifted into the ATM (antecedents, triggers, and mediators) portion of the investigation. After describing the joint responsibilities for a deeper understanding (insight) regarding her GI maladies, we moved to the questions regarding antecedents for her condition. She denied any family history of similar GI illnesses in her siblings. I then asked the question: *"When was the present problem not a problem? That is, when were you free of the problem and what were the circumstances of the problem's first appearance?"*

At this point, our conversation stopped. She looked a bit flummoxed and asked to consider the question further and more fully answer it when she next returned. At her next appointment, she returned to the question, stating that she wanted to share an experience that preceded her first episode of GI irritability. She said that she had not shared this story with any physician before in the context of the clinical workups for her GI problems. She then told the following story:

I left home at an early age to escape my father. He sexually abused me and my sisters. There did not seem to be any way to stop him; my mother seemed powerless, even when she walked into an abusive episode. In desperation, I left my sisters and my family, married and moved away.

My mother called me one afternoon, years after my leaving home. By that time I was a mother myself, having married and started my own family. My mother was quite upset and related that one of my sisters had arrived at her door, confronting her with the accusation of my father's sexual abuse of her in childhood and the lack of protection by our mother. My mother was adamant in her denial of knowledge of such wrongdoing by my father (my father had died in the intervening years since my leaving home).

I was silent for a moment on the phone with my mother. I then made a choice to placate my mother; I responded to her distress with a lie: "Mother, you know how my sister is; she is so hysterical."

My response seemed to settle my mother down. However, now that you have asked, this was the beginning of my gut problems. I stuffed that lie about our childhood with our father deep down into my gut and my gut has not been normal since.

Outcome: My patient’s therapy for her GI problems has been guided by both this insight regarding the origins of her illness as well as by my professional expertise in the area of both mind-body connections and GI physiology. Her therapeutic interventions focused on the 4R functional medicine approach to GI dysfunctions³⁴² and EMDR psychotherapeutic modalities developed for PTSD³⁴³ (an approach that has emerged from work with returning GIs from the Gulf War and the Afghanistan and Iraq conflicts). She now reports no further problems referable to her GI tract.

Our healing partnership helped elicit the insights that focused our attention on a fundamental issue that was critical to her healing. Without the supportive, mindful context that encouraged her insight to emerge, we would not have had the comprehensive patient story that was necessary for resolution of her problems. In this journey together, both left-brain computation (clinical and scientific evidence about the importance of the 4R GI dysfunction program and EMDR therapy in the context of PTSD) and right-brain functionality (a context for insight) were necessary.

As described in Chapter 4, insight researchers call this “aha” experience the *moment of categorical insight*. The epiphany registers as a new pattern of neural activity in the prefrontal cortex. The brain cells have been altered by the breakthrough. An insight is a restructuring of information—it’s seeing something in a completely new way. Once that restructuring occurs, you never go back.³⁴⁴

Summary

At The Institute for Functional Medicine (IFM) we believe that functional medicine exemplifies a systems-oriented, personalized medicine that recognizes the common underlying mechanisms of complex and chronic diseases that cut across multiple organ systems to shape a patient’s trajectory toward health or disease. IFM’s model of comprehensive care and primary prevention for complex, chronic illnesses is grounded in both science (the Functional Medicine Matrix Model; evidence about common underlying mechanisms and pathways of disease; evidence about effective approaches to the environmental and lifestyle sources of disease) and art (the *healing partnership* and the search for insight in the therapeutic encounter). We have shown how this approach offers both a conceptual model and pragmatic tools that help to integrate the best of emerging models in both conventional and integrative medicine. When practiced with an explicit emphasis on the importance of pattern-recognition and heuristic competencies inherent to right-brain function, a healing partnership can flourish, insight can be achieved, and a broad array of assessment and therapeutic tools can be utilized. We can produce a *mindful* medical practice paradigm shift that can encompass the uniqueness of each person, deriving probabilities that are clinically meaningful.

As articulated in Gerd Gigerenzer's thoughtful book, *Rationality for Mortals: How People Cope with Uncertainty*, heuristic processing (right brain) and statistical thinking (left brain) are "complementary mental tools, not mutually exclusive strategies; our minds need both."³⁴⁵ Through this uniting of competencies, we can incorporate the strengths of both science and art to craft an effective, personalized, and integrative approach to patient care. Without both elements steadily at work, we will find it exceptionally difficult to address successfully the epidemic of chronic disease that is the challenge of 21st century medicine.

What's Ahead?

Over the past few years, 33 medical schools and graduate nutrition programs plus 13 medical residency programs have sent attendees for training with IFM. These faculty, residents, fellows, and students have returned to their home institutions as strong advocates for functional medicine. They have helped to guide us toward key decision makers and have coached us on useful strategies. Thanks to these relationships, significant progress has been made to introduce functional medicine into medical schools and residency programs. Early funding has been secured and strategies, timelines, delivery formats (grand rounds, guest lectures, Webinars, print/online course materials), faculty training, and other issues are now being worked out.

Several elective courses in functional medicine have already been offered or are in the planning stages. As we bring the current discussion to a close, we'd like to reiterate that the ultimate goal of this entire project is to inspire system-wide change. We look forward to a transformation in health professions education and clinical practice that will help us conquer the 21st century challenge of chronic disease with as much efficacy as the 20th century brought to acute care. The change is imminent, it is urgently needed, and it is entirely possible.

ABOUT THE INSTITUTE FOR FUNCTIONAL MEDICINE

The Institute for Functional Medicine (IFM) is a nonprofit, tax-exempt 501(c)3 educational organization that educates physicians and other healthcare practitioners in improving the assessment and management of complex, chronic disease through the use of functional medicine. The Institute's mission is threefold: to develop the functional medicine knowledge base as a bridge between research (both emerging and established) and clinical practice; to educate physicians and other healthcare providers in the basic science and clinical applications of functional medicine; and to communicate with policy makers, practitioners, educators, researchers, and the public to disseminate the functional medicine knowledge base more widely. IFM has developed a model of comprehensive care and primary prevention for complex, chronic illness that is grounded in both the science (the *Functional Medicine Matrix Model*) and the art (the *healing partnership* in the therapeutic encounter) of clinical medicine that is now being implemented by functional medicine practitioners around the world.

The Institute for Functional Medicine is accredited by the Accreditation Council for Continuing Medical Education (ACCME) to provide continuing medical education for physicians. IFM offers educational publications and programs designed to raise the bar on clinicians' standard of care. Programs such as IFM's Functional Medicine Certification Program and Applying Functional Medicine in Clinical Practice (AFMCP) provide comprehensive clinical training for the assessment, treatment, prevention, and management of patients with complex, chronic disease. Other programs include IFM's Advanced Practice Modules, online Webinars, and the annual International Symposia on functional medicine. The Institute publishes textbooks, monographs, and other educational materials available for CME credits and offers clinicians a Forum for the shared exploration of emerging research and clinical applications to improve patient care and outcomes. Detailed information about the Institute, its educational activities, and membership can be found at www.functionalmedicine.org.

Author David S. Jones, MD is the President of The Institute for Functional Medicine. He has practiced as a family physician with emphasis in functional and integrative medicine for over 25 years. He is a recognized expert in the areas of nutrition, lifestyle changes for optimal health, and managed care, as well as the daily professional functions consistent with the modern specialty of family practice. He is the Editor-in-Chief of the *Textbook of Functional Medicine*. Laurie Hofmann, MPH, is IFM's Executive Director and an advisor and consultant to several public healthcare and health education initiatives across the country. Sheila Quinn is consulting author and editor of *21st Century Medicine: A New Model for Medical Education and Practice* and has contributed to many other IFM publications including the *Textbook of Functional Medicine*.

For information on obtaining additional copies of *21st Century Medicine* or to join us in IFM's vision and mission as a functional medicine practitioner, member, advocate, or sponsor, we invite you to visit our Web site, www.functionalmedicine.org, call us at 800-228-0622, or write us at client_services@fxmed.com. To contact the authors of *21st Century Medicine* or to submit comments or questions on this publication, please write to David S. Jones, MD at DavidJones@fxmed.com.

RECOMMENDATIONS FROM THE FUTURE OF FAMILY MEDICINE PROJECT

(<http://www.futurefamilymed.org/x24878.html>)

New Model of Family Medicine

Family medicine will redesign the work and workplaces of family physicians. This redesign will foster a New Model of Care based on the concept of a relationship-centered personal medical home, which serves as the focal point through which all individuals — regardless of age, gender, race, ethnicity, or socioeconomic status participate in health care. In this new medical home, patients receive a basket of services of acute, chronic, and preventive medical care services that are accessible, accountable, comprehensive, integrated, patient-centered, safe, scientifically valid, and satisfying to both patients and their physicians. This New Model will include technologies that enhance diagnosis and treatment for a large portion of problems that people bring to their family physicians. Business plans and reimbursement models will be developed to enable the reengineered practices of family physicians to thrive as personal medical homes, and resources will be developed to help patients make informed decisions about choosing a personal medical home. A financially self-sustaining national resource will be implemented to provide practices with ongoing support in transitioning to the New Model of Family Medicine.

Communications

A unified communications strategy will be developed to promote an awareness and understanding of the New Model of Family Medicine and the concept of a Personal Medical Home. As part of this strategy, a new symbol for family physicians will be created, and consistent terminology will be established for the specialty, (“family medicine” rather than “family practice” and “family physician” rather than “family practitioner”). In addition, a system will be developed to communicate and implement best practices within family medicine.

Electronic Health Records

Electronic health records that support the New Model of family medicine will be implemented. The electronic health record will enhance and integrate communication, diagnosis and treatment, measurement of processes and results, analysis of the effects of co-morbidity, recording and coding elements of whole-person care, and promoting ongoing, healing relationships between family physicians and their patients.

Family Medicine Education

Family medicine will oversee the training of family physicians who are committed to excellence, steeped in the core values of the discipline, expert in providing family medicine’s basket of services within the New Model of Family Medicine, skilled at adapting to varying patient and community needs, and prepared to

embrace new evidence-based technologies. Family medicine education will continue to include training in maternity care, the care of hospitalized patients, community and population health, and culturally effective and proficient care. Innovation in family medicine residency programs will be supported by the Residency Review Committee for Family Practice through 5-10 years of curricular flexibility to permit active experimentation and ongoing critical evaluation of competency-based education, expanded training programs and other strategies to prepare graduates for the New Model. In preparation for this process, every family medicine residency will implement electronic health records by 2006.

Life-Long Learning

The discipline of family medicine will develop a comprehensive, life-long learning program. This program will provide the tools for each family physician to create a continuous personal, professional, and clinical practice assessment and improvement plan that supports a succession of career stages. This personalized learning and professional development will include self-assessment and learning modules directed at individual physicians and group practices that incorporate science-based knowledge into educational interventions that foster improved patient outcomes. Family medicine residency programs and departments will incorporate continuing professional development into their curricula and will initiate and model the support process for life-long learning and maintenance of certification.

Enhancing the Science of Family Medicine

Participation in the generation of new knowledge will be integral to the activities of all family physicians and will be incorporated into family medicine training. Practice-based research will be integrated into the values, structures and processes of family medicine practices. Departments of family medicine will engage in highly collaborative research that produces new knowledge about the origins of disease and illness, how health is gained and lost, and how the provision of care can be improved. A national entity should be established to lead and fund research on the health and health care of whole people. Funding for the Agency for Healthcare Research and Quality should be increased to at least \$1 billion per year.

Quality of Care

Close working partnerships will be developed between academic family medicine, community-based family physicians and other partners in order to address the quality goals specified in the IOM's Quality Chasm report. Family physicians and their practice partners will have support systems to measure and report regularly their performance on the 6 IOM aims of quality health care (safe, timely, effective, equitable, patient-centered, and efficient). Family med residency programs will track and report regularly the performance of their residents during their training on the 6 IOM quality measures and will modify their training programs as necessary to improve performance.

Role of Family Medicine in Academic Health Centers

Departments of family medicine will individually and collectively analyze their position within the academic health center setting and will take steps to enhance their contribution to the advancement and rejuvenation of the AHC to meet the needs of the American people. A summit of policymakers and family medicine leaders in academia and private practice will be convened to review the role of and make recommendations on the future of family medicine in academia.

Promoting a Sufficient Family Medicine Workforce

A comprehensive Family Medicine Career Development Program and other strategies will be implemented to recruit and train a culturally diverse family physician workforce that meets the needs of the evolving US population for integrated health care for whole people, families and communities. Departments of family medicine will continue to develop, implement, disseminate and evaluate best practices in expanding student interest in the specialty.

Leadership and Advocacy

Recommendation #10 from the Future of Family Medicine Report concerned Leadership and Advocacy. The Strategic Initiative calls for: A Leadership Center for Family Medicine and Primary Care will be established which will develop strategies to promote family physicians and other primary care physicians as health policy and research leaders in their communities, in government, and in other influential groups. In their capacity as leaders, family physicians will convene leaders to identify and develop implementation strategies for several major policy initiatives, including assuring that every American has access to basic health care services. Family physicians will partner with others at the local, state and national levels to engage patients, clinicians and payers in advocating for a redesigned system of integrated, personalized, equitable and sustainable health care.

JOINT PRINCIPLES OF THE PATIENT-CENTERED MEDICAL HOME

February 2007

American Academy of Family Physicians (AAFP)

American Academy of Pediatrics (AAP)

American College of Physicians (ACP)

American Osteopathic Association (AOA)

Introduction

The Patient-Centered Medical Home (PC-MH) is an approach to providing comprehensive primary care for children, youth and adults. The PC-MH is a health care setting that facilitates partnerships between individual patients, and their personal physicians, and when appropriate, the patient's family. The AAP, AAFP, ACP, and AOA, representing approximately 333,000 physicians, have developed the following joint principles to describe the characteristics of the PC-MH.

Principles

Personal physician – each patient has an ongoing relationship with a personal physician trained to provide first contact, continuous and comprehensive care.

Physician directed medical practice – the personal physician leads a team of individuals at the practice level who collectively take responsibility for the ongoing care of patients.

Whole person orientation – the personal physician is responsible for providing for all the patient's health care needs or taking responsibility for appropriately arranging care with other qualified professionals. This includes care for all stages of life; acute care; chronic care; preventive services; and end of life care.

Care is coordinated and/or integrated across all elements of the complex health care system (e.g., subspecialty care, hospitals, home health agencies, nursing homes) and the patient's community (e.g., family, public and private community-based services). Care is facilitated by registries, information technology, health information exchange and other means to assure that patients get the indicated care when and where they need and want it in a culturally and linguistically appropriate manner.

Quality and safety are hallmarks of the medical home:

- ⊗ Practices advocate for their patients to support the attainment of optimal, patient-centered outcomes that are defined by a care planning process driven by a compassionate, robust partnership between physicians, patients, and the patient's family.
- ⊗ Evidence-based medicine and clinical decision-support tools guide decision making
- ⊗ Physicians in the practice accept accountability for continuous quality improvement through voluntary engagement in performance measurement and improvement.

- ⊕ Patients actively participate in decision-making and feedback is sought to ensure patients' expectations are being met
- ⊕ Information technology is utilized appropriately to support optimal patient care, performance measurement, patient education, and enhanced communication
- ⊕ Practices go through a voluntary recognition process by an appropriate non-governmental entity to demonstrate that they have the capabilities to provide patient centered services consistent with the medical home model.
- ⊕ Patients and families participate in quality improvement activities at the practice level.

Enhanced access to care is available through systems such as open scheduling, expanded hours and new options for communication between patients, their personal physician, and practice staff.

Payment appropriately recognizes the added value provided to patients who have a patient-centered medical home. The payment structure should be based on the following framework:

- ⊕ It should reflect the value of physician and non-physician staff patient-centered care management work that falls outside of the face-to-face visit.
- ⊕ It should pay for services associated with coordination of care both within a given practice and between consultants, ancillary providers, and community resources.
- ⊕ It should support adoption and use of health information technology for quality improvement;
- ⊕ It should support provision of enhanced communication access such as secure e-mail and telephone consultation;
- ⊕ It should recognize the value of physician work associated with remote monitoring of clinical data using technology.
- ⊕ It should allow for separate fee-for-service payments for face-to-face visits. (Payments for care management services that fall outside of the face-to-face visit, as described above, should not result in a reduction in the payments for face-to-face visits).
- ⊕ It should recognize case mix differences in the patient population being treated within the practice.
- ⊕ It should allow physicians to share in savings from reduced hospitalizations associated with physician-guided care management in the office setting.
- ⊕ It should allow for additional payments for achieving measurable and continuous quality improvements.

Background of the Medical Home Concept

The American Academy of Pediatrics (AAP) introduced the medical home concept in 1967, initially referring to a central location for archiving a child's medical record. In its 2002 policy statement, the AAP expanded the medical home concept to include these operational characteristics: accessible, continuous, comprehensive, family-centered, coordinated, compassionate, and culturally effective care. The American Academy of Family Physicians (AAFP) and the American College of Physicians (ACP) have since developed their own models for improving patient care called the "medical home" (AAFP, 2004) or "advanced medical home" (ACP, 2006).

INSTITUTE FOR SYSTEMS BIOLOGY, SEATTLE, WA

From their website and used with their permission: http://www.systemsbiology.org/Intro_to_ISB_and_Systems_Biology/Predictive_Preventive_Personalized_and_Participatory

The goal of systems biology is to fundamentally transform the practice of medicine, and ISB researchers have taken the leadership role in catalyzing this transformation. We are developing tools and techniques, and pursuing research that will usher in a new era of predictive, preventive, and personalized medicine.

Today's medicine is reactive: we wait until someone is sick before administering treatment. Medicine of the future will be predictive and preventive, examining the unique biology of an individual to assess their probability of developing various diseases and then designing appropriate treatments, even before the onset of a disease. Today's medicine is also myopic: we use only a few measurements to diagnose disease and are generally unable to make fine distinctions between individuals or between subtle variations of the same disease. Medicine of the future will use more sophisticated measurements, as well as more measurements overall, thereby yielding accurate health assessments for truly personalized treatments.

Improved personal measurements and personalized treatments are the keys to improving health care. Diseases arise from either genetic abnormalities, detrimental environmental factors (poor diet, infectious organisms, or toxins), or a combination of these. We know certain genetic patterns can make a person unusually susceptible to factors in their environment. We also know certain defective genes will increase the probability of an individual having certain health problems. For example, a woman with a single copy of the mutant breast cancer 1 gene (BRCA-1) has a 70 percent chance of developing breast cancer by the time she's 60 years old. Unfortunately, today there is no practical way for each of us to determine our genetic makeup and, more important, to understand the likely health consequences. However, in the future individuals will be able to easily obtain such information, and then work closely with their health practitioner to develop a predictive, preventive and personalized health-care program.

Prediction. The technologies and tools of systems biology will provide medical practitioners with two exciting sources of health-related diagnostic data: By examining an individual's complete genetic makeup, a physician will be able to generate comprehensive predictions about the patient's health prospects. And by examining protein markers which naturally occur in an individual's blood, a physician will be able to accurately determine a person's health status, including both the current effects of any abnormal genes and the current reactions to any environmental toxins or infectious pathogens.

Prevention. The new approach to medicine, based on each individual's genetic makeup, will help us determine the probability of an individual contracting certain diseases, as well as reveal how an individual may respond to various treatments, thereby providing guidance for developing customized therapeutic drugs. Thus another use of the technologies and tools of systems biology will be to develop preventive treatments for individuals, based on their potential health problems, as indicated by their genetic makeup and current blood- protein markers.

The goal of this new approach to medicine will be to use the most fundamental health-related information—an individual's genetic makeup plus current health status (as identified by blood protein markers)—to prescribe appropriate preventive drugs. For example, given your genetic makeup, you may have a 40% chance of developing breast cancer by age 50, but if you start taking a certain drug at age 35, that chance could drop to 5% at age 50.

In fact, scientists at ISB are currently involved in several research programs involving blood diagnosis of complex diseases, including type I diabetes, breast cancer, and prostate cancer. Cancer is the second leading cause of death in the United States, with prostate cancer accounting for one third of all cancer cases among men, and breast cancer accounting for approximately half of all cancer cases among women. ISB scientists are currently researching protein markers which occur in blood to better identify the onset, metastatic potential, and probable course of these cancers in individuals, with the eventual goal of developing more effective treatments.

The common theme running through all of this research and its application to medicine—the predictive and preventive potential of systems biology—is **personalization**. On average, each human differs from another by less than one percent of their genetic makeup. But these genetic differences give rise to our physical differences, including our potential predisposition to various diseases. So the ability to examine each individual's unique genetic makeup and thereby customize our approaches to medical treatment is at the heart of this new era of predictive, preventive, personalized medicine.

As a result of this personalization, medicine will become **participatory**. Patients will actively participate in personal choices about illness and well-being. Participatory medicine will require the development of powerful new approaches for securely handling enormous amounts of personal information and for educating both patients and their physicians.

http://www.systemsbiology.org/Systems_Biology_in_Depth/Premise_of_Systems_Biology

The true test of a good system model is successful prediction of the system's behavior under targeted alterations (genetic or environmental perturbations) of experimental conditions. But the very properties that make biological systems interesting and worthwhile to study—their emergent properties, robustness, stability, modularity and adaptability to change, also make their behavior hard to predict at the molecular level. Confounding factors include functional redundancy (i.e., a given process might be accomplished by several different molecular mechanisms), and the stochasticity of cell populations (what is measured, e.g., gene expression, could be an average of a wide range of discrete responses among individual cells).

Systems biologists approach this conundrum by adopting the following principles:

1. Global approaches should be taken to data collection and analyses. Ideally, high-throughput platforms are used to collect accurate measurements under multiple sets of well-defined experimental conditions. Technologies for performing quantitative, multi parameter measurements on a single sample need to be developed. To add value to the analyses of data

obtained from multiplex technologies such as chips and panels of gene deletion mutants or RNAi gene knockouts, global approaches will incorporate relevant findings from curated databases and the published literature.

2. Information derived from diverse data types should be integrated. Systems biology derives power from the leveraging of pre-existing biochemical and cell biology knowledge with the various interaction network models inferred from the global datasets. Even though each source of data type might be sparse, noisy, or contain systematic errors, a meaningful pattern among the diverse data might become apparent and further analysis made possible if the network models are integrated.
3. Mathematical and statistical modeling is essential to the quantitative analysis of a system's properties. Based on a working model and relevant assumptions, computer simulations are used to probe the probable effects of perturbations on a system's components and interactions in the interest of making predictions that can be validated by the collection of more data. Thus, there is a tight integration of computer modeling with experimental design.
4. Biology should drive technology which, in turn, makes better biology possible. Invention of novel or more sophisticated data collection, analysis and modeling tools is motivated by the need to solve a real-world biological problem. As a paradigm case, the Human Genome Project forced the development of high-throughput DNA sequencing methodologies. The need to perform multiparameter measurements on single cells is currently driving the invention of microfluidic/nanotechnology devices.
5. Systems biology research should create an interactive inter-disciplinary scientific culture. For progress to occur, experts in engineering, physics, mathematics, and computer science must join biochemists, cell biologists, and physiologists in the effort to figure out how to obtain the required data and develop the sophisticated computational approaches that will be needed to make viable predictions. For scientists who have been trained primarily in one of these disciplines, doing systems biology research involves stepping outside one's comfort zone to learn new concepts and methodologies. Systems biology-focused institutions accept that cross-disciplinary training from the get-go is the best way for new investigators to embrace the field.
6. The results of research should be freely disseminated. The Human Genome Project has revealed the enormous benefit that derives from the public release of data to the community of researchers. While not as easy to work with as genomic sequence, available microarray datasets, yeast two-hybrid analyses, collections of gene knockout strains and the like have accelerated progress in systems biology research. Similarly, computational biology is facilitated by the sharing of open-source software.

DEFINITION OF EVIDENCE-BASED MEDICINE

What is EBM?

This article is based on an editorial from the British Medical Journal on 13th January 1996 (BMJ 1996; 312: 71-2)

Brief definition:

Evidence-based medicine is the conscientious, explicit and judicious use of current best evidence in making decisions about the care of individual patients. The practice of evidence-based medicine means integrating individual clinical expertise with the best available external clinical evidence from systematic research.

Expanded definition:

Evidence-Based Medicine, whose philosophical origins extend back to mid-19th century Paris and earlier, remains a hot topic for clinicians, public health practitioners, purchasers, planners, and the public. There are now frequent workshops in how to practice and teach it (one sponsored by this journal will be held in London on April 24th); undergraduate [1] and post-graduate training programmes [2] are incorporating it [3] (or pondering how to do so); British centres for evidence-based practice have been established or planned in adult medicine, child health, surgery, pathology, pharmacotherapy, nursing, general practice, and dentistry; the Cochrane Collaboration and the York Centre for Review and Dissemination in York are providing systematic reviews of the effects of health care; new evidence-based practice journals are being launched; and it has become a common topic in the lay media. But enthusiasm has been mixed with some negative reaction [4-6]. Criticism has ranged from evidence-based medicine being old-hat to it being a dangerous innovation, perpetrated by the arrogant to serve cost-cutters and suppress clinical freedom. As evidence-based medicine continues to evolve and adapt, now is a useful time to refine the discussion of what it is and what it is not.

Evidence-based medicine is the conscientious, explicit and judicious use of current best evidence in making decisions about the care of individual patients. The practice of evidence-based medicine means integrating individual clinical expertise with the best available external clinical evidence from systematic research. By individual clinical expertise we mean the proficiency and judgement that individual clinicians acquire through clinical experience and clinical practice. Increased expertise is reflected in many ways, but especially in more effective and efficient diagnosis and in the more thoughtful identification and compassionate use of individual patients' predicaments, rights, and preferences in making clinical decisions about their care. By best available external clinical evidence we mean clinically relevant research, often from the basic sciences of medicine, but especially from patient centred clinical research into the accuracy and precision of diagnostic tests (including the clinical examination), the power of prognostic

markers, and the efficacy and safety of therapeutic, rehabilitative, and preventive regimens. External clinical evidence both invalidates previously accepted diagnostic tests and treatments and replaces them with new ones that are more powerful, more accurate, more efficacious, and safer.

Good doctors use both individual clinical expertise and the best available external evidence, and neither alone is enough. Without clinical expertise, practice risks becoming tyrannised by evidence, for even excellent external evidence may be inapplicable to or inappropriate for an individual patient. Without current best evidence, practice risks becoming rapidly out of date, to the detriment of patients.

This description of what evidence-based medicine is helps clarify what evidence-based medicine is not. Evidence-based medicine is neither old-hat nor impossible to practice. The argument that everyone already is doing it falls before evidence of striking variations in both the integration of patient values into our clinical behaviour [7] and in the rates with which clinicians provide interventions to their patients [8]. The difficulties that clinicians face in keeping abreast of all the medical advances reported in primary journals are obvious from a comparison of the time required for reading (for general medicine, enough to examine 19 articles per day, 365 days per year [9]) with the time available (well under an hour per week by British medical consultants, even on self-reports [10]).

The argument that evidence-based medicine can be conducted only from ivory towers and armchairs is refuted by audits in the front lines of clinical care where at least some inpatient clinical teams in general medicine [11], psychiatry (JR Geddes, et al, Royal College of Psychiatrists winter meeting, January 1996), and surgery (P McCulloch, personal communication) have provided evidence-based care to the vast majority of their patients. Such studies show that busy clinicians who devote their scarce reading time to selective, efficient, patient-driven searching, appraisal and incorporation of the best available evidence can practice evidence-based medicine.

Evidence-based medicine is not “cook-book” medicine. Because it requires a bottom-up approach that integrates the best external evidence with individual clinical expertise and patient-choice, it cannot result in slavish, cook-book approaches to individual patient care. External clinical evidence can inform, but can never replace, individual clinical expertise, and it is this expertise that decides whether the external evidence applies to the individual patient at all and, if so, how it should be integrated into a clinical decision. Similarly, any external guideline must be integrated with individual clinical expertise in deciding whether and how it matches the patient’s clinical state, predicament, and preferences, and thus whether it should be applied. Clinicians who fear top-down cook-books will find the advocates of evidence-based medicine joining them at the barricades.

Evidence-based medicine is not cost-cutting medicine. Some fear that evidence-based medicine will be hijacked by purchasers and managers to cut the costs of health care. This would not only be a misuse of evidence-based medicine but suggests a fundamental misunderstanding of its financial consequences. Doctors practising evidence-based medicine will identify and apply the most efficacious interventions to maximise the quality and quantity of life for individual patients; this may raise rather than lower the cost of their care.

Evidence-based medicine is not restricted to randomised trials and meta-analyses. It involves tracking down the best external evidence with which to answer our clinical questions. To find out about the accuracy of a diagnostic test, we need to find proper cross-sectional studies of patients clinically suspected of harbouring the relevant disorder, not a randomised trial. For a question about prognosis, we need proper follow-up studies of patients assembled at a uniform, early point in the clinical course of their disease. And sometimes the evidence we need will come from the basic sciences such as genetics or immunology. It is when asking questions about therapy that we should try to avoid the non-experimental approaches, since these routinely lead to false-positive conclusions about efficacy. Because the randomised trial, and especially the systematic review of several randomised trials, is so much more likely to inform us and so much less likely to mislead us, it has become the “gold standard” for judging whether a treatment does more good than harm. However, some questions about therapy do not require randomised trials (successful interventions for otherwise fatal conditions) or cannot wait for the trials to be conducted. And if no randomised trial has been carried out for our patient’s predicament, we follow the trail to the next best external evidence and work from there.

Despite its ancient origins, evidence-based medicine remains a relatively young discipline whose positive impacts are just beginning to be validated [12, 13], and it will continue to evolve. This evolution will be enhanced as several undergraduate, post-graduate, and continuing medical education programmes adopt and adapt it to their learners’ needs. These programmes, and their evaluation, will provide further information and understanding about what evidence-based medicine is, and what it is not.

INFORMATION ABOUT THE CHRONIC CARE MODEL

from www.improvingchroniccare.org

With the exception of the Chronic Care Model image, all materials and text found on our Web site may be freely used and disseminated. No official permission is needed from ICIC. Certain tools, developed by ICIC, have a copyright attached in order for us to retain the right to distribute and make revisions to the work.

Reprint permission is required for use of the Chronic Care Model image. Copyright is held by the American College of Physicians (ACP), which publishes the Annals of Internal Medicine journal. The CCM image first appeared in its current format in the Effective Clinical Practice article **Chronic Disease Management: What Will It Take To Improve Care for Chronic Illness?** published in August/September of 1998. Used with permission.

Promoting effective change in provider groups to support evidence-based clinical and quality improvement across a wide variety of health care settings.

There are many definitions of “chronic condition,” some more expansive than others. We characterize it as any condition that requires ongoing adjustments by the affected person and interactions with the health care system.

133 million people, or almost half of all Americans, live with a chronic condition. ¹ That number is projected to increase by more than one percent per year by 2030, resulting in an estimated chronically ill population of 171 million.

Almost half of all people with chronic illness have multiple conditions. As a result, many managed care and integrated delivery systems have taken a great interest in correcting the many deficiencies in current

management of diseases such as diabetes, heart disease, depression, asthma and others. 2, 3, 4

Those deficiencies include:

- ⊗ Rushed practitioners not following established practice guidelines
- ⊗ Lack of care coordination
- ⊗ Lack of active follow-up to ensure the best outcomes
- ⊗ Patients inadequately trained to manage their illnesses

Overcoming these deficiencies will require nothing less than a transformation of health care, from a system that is essentially reactive - responding mainly when a person is sick - to one that is proactive and focused on keeping a person as healthy as possible. (5, 6, 7) To speed the transition, Improving Chronic Illness Care created the Chronic Care Model, which summarizes the basic elements for improving care in health systems at the community, organization, practice and patient levels.

Model Elements

The Chronic Care Model (CCM) identifies the essential elements of a health care system that encourage high-quality chronic disease care. These elements are the community, the health system, self-management support, delivery system design, decision support and clinical information systems. Evidence-based change concepts under each element, in combination, foster productive interactions between informed patients who take an active part in their care and providers with resources and expertise.

The Model can be applied to a variety of chronic illnesses, health care settings and target populations. The bottom line is healthier patients, more satisfied providers, and cost savings.

Development of the Chronic Care Model

The staff at the MacColl Institute for Healthcare Innovation developed the CCM by drawing on available literature about promising strategies for chronic illness management, and organizing that literature in a new more accessible way. The Model was further refined during a nine-month planning project supported by The Robert Wood Johnson Foundation, and revised based on input from a large panel of national experts. It was then used to collect data and analyze innovative programs recommended by experts. RWJF funded the MacColl Institute to test the Model nationally across varied health care settings, creating the national program, “Improving Chronic Illness Care” (ICIC).

Refinements to the Chronic Care Model

In 2003, ICIC and a small group of experts updated the CCM to reflect advances in the field of chronic care both from the research literature and from the scores of health care systems that implemented the Model in their improvement efforts. We list more specific concepts under each of the six elements. Based on more

recent evidence, five new themes were incorporated into the CCM:

- ⊗ Patient Safety (in Health System);
- ⊗ Cultural competency (in Delivery System Design);
- ⊗ Care coordination (in Health System and Clinical Information Systems)
- ⊗ Community policies (in Community Resources and Policies); and
- ⊗ Case management (in Delivery System Design).

The Model element pages have been redesigned to reflect these updates. Each page describes the overall strategy for each element, and the health system change concepts necessary to achieve improvement in that component. The refinements have been emphasized in bold typeface for ready identification.

Health System

Create a culture, organization and mechanisms that promote safe, high quality care

- ⊗ Visibly support improvement at all levels of the organization, beginning with the senior leader
- ⊗ Promote effective improvement strategies aimed at comprehensive system change
- ⊗ Encourage open and systematic handling of errors and quality problems to improve care
- ⊗ Provide incentives based on quality of care
- ⊗ Develop agreements that facilitate care coordination within and across organizations

A system seeking to improve chronic illness care must be motivated and prepared for change throughout the organization. Senior leadership must identify care improvement as important work, and translate it into clear improvement goals and policies that are addressed through application of effective improvement strategies, including use of incentives, that encourage comprehensive system change. Effective organizations try to prevent errors and care problems by reporting and studying mistakes and making appropriate changes to their systems. Breakdowns in communication and care coordination can be prevented through agreements that facilitate communication and data-sharing as patients navigate across settings and providers.

Delivery System Design

Assure the delivery of effective, efficient clinical care and self-management support

- ⊗ Define roles and distribute tasks among team members

- ⊗ Use planned interactions to support evidence-based care
- ⊗ Provide clinical case management services for complex patients
- ⊗ Ensure regular follow-up by the care team
- ⊗ Give care that patients understand and that fits with their cultural background

Improving the health of people with chronic illness requires transforming a system that is essentially reactive - responding mainly when a person is sick - to one that is proactive and focused on keeping a person as healthy as possible. That requires not only determining what care is needed, but spelling out roles and tasks for ensuring the patient gets care using structured, planned interactions. And it requires making follow-up a part of standard procedure, so patients aren't left on their own once they leave the doctor's office. 5,6,7 More complex patients may need more intensive management (care or case management) for a period of time to optimize clinic care and self-management. Health literacy and cultural sensitivity are two important emerging concepts in health care. Providers are increasingly being called upon to respond effectively to the diverse cultural and linguistic needs of patients.

Decision Support

Promote clinical care that is consistent with scientific evidence and patient preferences

- ⊗ Embed evidence-based guidelines into daily clinical practice
- ⊗ Share evidence-based guidelines and information with patients to encourage their participation
- ⊗ Use proven provider education methods
- ⊗ Integrate specialist expertise and primary care

Treatment decisions need to be based on explicit, proven guidelines supported by clinical research. Guidelines should also be discussed with patients, so they can understand the principles behind their care. Those who make treatment decisions need ongoing training to stay up-to-date on the latest evidence, using new models of provider education that improve upon traditional continuing medical education. To change practice, guidelines must be integrated through timely reminders, feedback, standing orders and other methods that increase their visibility at the time that clinical decisions are made. The involvement of supportive specialists in the primary care of more complex patients is an important educational modality.

Clinical Information Systems

Organize patient and population data to facilitate efficient and effective care

- ⊗ Provide timely reminders for providers and patients

- ⊗ Identify relevant subpopulations for proactive care
- ⊗ Facilitate individual patient care planning
- ⊗ Share information with patients and providers to coordinate care
- ⊗ Monitor performance of practice team and care system

Effective chronic illness care is virtually impossible without information systems that assure ready access to key data on individual patients as well as populations of patients. 11, 12 A comprehensive clinical information system can enhance the care of individual patients by providing timely reminders for needed services, with the summarized data helping to track and plan care. At the practice population level, an information system can identify groups of patients needing additional care as well as facilitate performance monitoring and quality improvement efforts.

Self-Management Support

Empower and prepare patients to manage their health and health care

- ⊗ Emphasize the patient's central role in managing their health
- ⊗ Use effective self-management support strategies that include assessment, goal-setting, action planning, problem-solving and follow-up
- ⊗ Organize internal and community resources to provide ongoing self-management support to patients

All patients with chronic illness make decisions and engage in behaviors that affect their health (self-management). Disease control and outcomes depend to a significant degree on the effectiveness of self-management.

Effective self-management support means more than telling patients what to do. It means acknowledging the patients' central role in their care, one that fosters a sense of responsibility for their own health. It includes the use of proven programs that provide basic information, emotional support, and strategies for living with chronic illness. Self-management support can't begin and end with a class. Using a collaborative approach, providers and patients work together to define problems, set priorities, establish goals, create treatment plans and solve problems along the way.⁹

The Community

Mobilize community resources to meet needs of patients

- ⊗ Encourage patients to participate in effective community programs

- ☉ Form partnerships with community organizations to support and develop interventions that fill gaps in needed services
- ☉ Advocate for policies to improve patient care

By looking outside of itself, the health care system can enhance care for its patients and avoid duplicating effort. Community programs can support or expand a health system's care for chronically ill patients, but systems often don't make the most of such resources. A health system might form a partnership with a local senior center that provides exercise classes as an option for elderly patients. State departments of health and other agencies often have a wealth of helpful material available for the asking - wallet cards with tips for controlling diabetes, for example. National patient organizations such as the American Diabetes Association can help by promoting self-help strategies.

Local and state health policies, insurance benefits, civil rights laws for persons with disabilities, and other health-related regulations also play a critical role in chronic illness care. Advocacy by medical organizations on behalf of their patients can make a difference.

EXCERPTS FROM *Patient-Centered Care: Antecedents, Triggers, and Mediators*

Chapter 8, Textbook of Functional Medicine

By Leo Galland, MD

The goal of person-centered diagnosis is to enable healers to develop individualized treatment plans that are based upon an understanding of the physiological, environmental, and psychosocial contexts within which each person's illnesses or dysfunctions occur.... you must start by eliciting all of the patient's concerns. In actively listening to the patient's story, you attempt to discover the **antecedents, triggers** and **mediators** that underlie symptoms, signs, illness behaviors, and demonstrable pathology. Functional medicine is based upon treatment that is collaborative, flexible, and focused on the control or reversal of each person's individual antecedents, triggers and mediators, rather than the treatment of disease entities.

It is the functional medicine practitioner's job to know not just the ailments or their diagnoses, but the physical and social environment in which sickness occurs, the dietary habits of the person who is sick (present diet and pre-illness diet), his beliefs about the illness, the impact of illness on social and psychological function, factors that aggravate or ameliorate symptoms, and factors that predispose to illness or facilitate recovery. This information is necessary for establishing a functional treatment plan.

What modern science has taught us about the genesis of disease can be represented by three words: triggers, mediators, and antecedents. Triggers are discrete entities or events that provoke disease or its symptoms. Microbes are an example. The greatest scientific discovery of the 19th century was the microbial etiology of the major epidemic diseases. Triggers are usually insufficient in and of themselves for disease formation, however. Host response is an essential component.

Identifying the biochemical mediators that underlie host responses was the most productive field of biomedical research during the second half of the 20th century. Mediators, as the word implies, do not "cause" disease. They are intermediaries that contribute to the manifestations of disease. Antecedents are factors that predispose to acute or chronic illness. For a person who is ill, they form the illness diathesis. From the perspective of prevention, they are risk factors. Knowledge of antecedents has provided a rational structure for the organization of preventive medicine and public health.

Medical genomics seeks to better understand disease by identifying the phenotypic expression of disease-related genes and their products. The application of genomic science to clinical medicine requires the integration of antecedents (genes and the factors controlling their expression) with mediators (the downstream products of gene activation). Mediators, triggers, and antecedents are not only key biomedical concepts, they are also important psychosocial concepts. In person-centered diagnosis, the mediators, triggers, and antecedents for each person's illness form the focus of clinical investigation.

Antecedents and the Origins of Illness

Understanding the antecedents of illness helps the physician understand the unique characteristics of each patient as they relate to his or her current health status. Antecedents may be thought of as congenital or developmental. The most important congenital factor is gender: women and men differ markedly in susceptibility to many disorders. The most important developmental factor is age; what ails children is rarely the same as what ails the elderly. Beyond these obvious factors lies a diversity as complex as the genetic differences and separate life experiences that distinguish one person from another.

Triggers and the Provocation of Illness

A trigger is anything that initiates an acute illness or the emergence of symptoms. The distinction between a trigger and a precipitating event is relative, not absolute; the distinction helps organize the patient's story. As a general rule, triggers only provoke illness as long as the person is exposed to them (or for a short while afterward), whereas a precipitating event initiates a change in health status that persists long after the exposure ends.

Common triggers include physical or psychic trauma, microbes, drugs, allergens, foods (or even the act of eating or drinking), environmental toxins, temperature change, stressful life events, adverse social interactions, and powerful memories. For some conditions, the trigger is such an essential part of our concept of the disease that the two cannot be separated; the disease is either named after the trigger (e.g., “Strep throat”) or the absence of the trigger negates the diagnosis (e.g., concussion cannot occur without head trauma). For chronic ailments like asthma, arthritis, or migraine headaches, multiple interacting triggers may be present. All triggers, however, exert their effects through the activation of host-derived mediators. In closed-head trauma, for example, activation of NMDA receptors, induction of nitric oxide synthase (iNOS), and liberation of free intra-neuronal calcium determine the late effects. Intravenous magnesium at the time of trauma attenuates severity by altering the mediator response.^{1,2} Sensitivity to different triggers often varies among persons with similar ailments. A prime task of the functional practitioner is to help patients identify important triggers for their ailments and develop strategies for eliminating them or diminishing their virulence.

Mediators and the Formation of Illness

A mediator is anything that produces symptoms, damage to tissues of the body, or the types of behaviors associated with being sick. Mediators vary in form and substance. They may be biochemical (like prostanooids and cytokines), ionic (like hydrogen ions), social (like reinforcement for staying ill), psychological (like fear), or cultural (like beliefs about the nature of illness). A list of common mediators is presented in Table 8.1. Illness in any single person usually involves multiple interacting mediators. Biochemical, psychosocial, and cultural mediators interact continuously in the formation of illness.

A New Model for Medical Education and Practice

PATTERN RECOGNITION: ULCERATIVE COLITIS		
Immune Surveillance		Practitioner's Notes
1	☐	Breastfed How long?
2	☐	Vaccinated Adverse reactions?
3	☐	Skin rashes
	☐	Reaction to contact with significant redness (dermatographia)?
4	☐	Joint swelling, redness
5	☐	Dry mouth, lack of salivation
6	☐	Dry eyes
7	☐	Migraines Triggered by foods _____ odors _____
8	☐	Cravings Fatigue after eating certain foods?
9	☐	Illness, dysfunction after flu-like or GI flu illness
10	☐	Neurological symptoms that developed slowly over the course of a day and then resolved after several weeks to months, clearing slowly ☐ Change in vision ☐ Coordination ☐ Numbness ☐ Cognitive problems
11	☐	Family history of autoimmune disease
12	☐	Multiple infections
13	☐	Non-specific increased mucus / allergic symptoms
14	☐	Fatigue
15	☐	Other:

PATTERN RECOGNITION: ULCERATIVE COLITIS			
Inflammatory Process			Practitioner's Notes
1	☐	Swelling ☐ Diffuse (edema) ☐ Localized (angioedema, papules, urticaria)	
2	☐	Erthema (hyperemia, rashes, erysipelas)	
3	☐	Heat ☐ systemic (fever) ☐ localized (warmth)	
4	☐	Pain (arthralgias, neuralgias, cramping)	
5	☐	Irritation (pruritis, sneezing, etc.)	
6	☐	Loss of function ☐ Associated with pain or scarring ☐ Cognitive impairment (neurodegeneration)	
7	☐	Excessive mucus or fluid production (includes bronchospasm, diarrhea, etc.)	
8	☐	Inflammatory markers ☐ Elevated CRP, ESR, WBC (microscopic or gross purulence) ☐ thrombocytosis ☐ fibrinogen ☐ inflammatory cytokines (IL-1, IL-6, TNF alpha), ☐ decreased complement split products, ☐ homocysteine ☐ lipoprotein A2 (PLAC) ☐ calprotectin (fecal or serum)	
9	☐	Autoantibodies (ANA, RF) or elevated immunoglobulins (abnormal SPEP, tissue transglutaminase IgG, etc.	
10	☐	Elevated free radical markers (lipid peroxides, F2 isoprostanes, 8-OH-d-G)	
11	☐	Hypercoagulability	
12	☐	Other:

PATTERN RECOGNITION: ULCERATIVE COLITIS		
Digestion, Absorption, Barrier Integrity		Practitioner's Notes
1	☐ Symptoms that arise around eating	
2	☐ Chew your food thoroughly and eat slowly or ☐ Eat quickly or on the run	
3	☐ Problems with saliva, such as dry mouth or drooling?	
4	☐ Experience early satiety, fullness with small portions ☐ Consistent discomfort after eating a typical meal	
5	☐ Frequent nausea Triggered by:_____	
6	☐ Gas or bloating	
7	☐ Burping, belching, gurgling, rumbling	
8	☐ Diagnosed with reflux disease (GERD)? Medication_____ x day, week	
9	☐ Diagnosed with peptic ulcers Antacids_____ x day, week	
10	☐ Tend toward either diarrhea (loose stools) or constipation? If so, which is more typical? Bowel movements_____ x day, week	
11	☐ Stool consistency varies_____ If so, which is more typical? Bowel movements_____ x day / week	
12	☐ Ever sweat intensely after eating certain foods or after meals?	
13	☐ Camp, raft or spend time in wilderness areas and if so, do you drink stream water?	
14	☐ Live with pets? If so, have they had gastrointestinal infections?	
15	☐ Other:	

PATTERN RECOGNITION: ULCERATIVE COLITIS		
Detoxification and Biotransformation		Practitioner's Notes
1	☐ Smoke_____ how much x day / week_____ ☐ Exposed regularly to secondhand smoke	
2	☐ Mercury amalgam fillings	
3	☐ Live or work in a densely populated area or near an industrial plant	
4	☐ Use of pesticides, herbicides, insecticides in the home or garden	
5	☐ Use of chemical preparations at work or as hobby	
6	☐ Breathe toxic elements in the air, fumes or other petrochemicals	
7	☐ Symptoms (fatigue, headaches, nausea) upon exposure to various chemicals (such as perfume, smoke, diesel or gas fumes, etc.)	
8	☐ Eat fish three times a week or more	
9	☐ Prone to problems taking most medications (overly sensitive to most medication and experience numerous side effects)	
10	☐ React quickly to dental anesthetics ☐ Require repeated administration of anesthetic ☐ Numbness of one shot lasts a long time	
11	☐ Other:

3	☐	Pains that diminish as the day progresses, returning the next AM	
	☐	Pains that increase as the day progresses, minimized the next AM	
4	☐	Pains impacted by posture	
5	☐	Pains impacted by repositioning the body (worse or better)	
6	☐	Postural abnormalities (head anterior to shoulders, swayback, tilted head, elevated shoulder, hip sway with gait, awkward gait)	
7	☐	Abnormal wear pattern of shoes	
8	☐	Abnormal (awkward) gait patterns	
9	☐	Stiffness in AM getting out of bed, relieved by a hot shower	
10	☐	Other:	

FUNCTIONAL MEDICINE CASE: PSORIATIC ARTHRITIS¹

Kara N. Fitzgerald, ND, and Mark Hyman, MD

Functional Medicine and Autoimmune Disease

Autoimmune diseases collectively affect up to 23.5 million Americans.¹ They are heterogeneous in pathology but relatively uniform in etiology. Classifying autoimmune diseases based on symptoms and pathology does not usually improve treatment decisions. Standard treatments include NSAIDs, steroids, anti-neoplastic agents, and tumor necrosis factor-alpha antagonists. These tools have significant risks and are often applied regardless of the diagnosis. Frequently, they are only modestly effective in relieving symptoms and limiting the advancing disease process. Despite the extensive categorization of autoimmune diseases into diagnoses such as lupus, rheumatoid arthritis, psoriatic arthritis, inflammatory bowel disease, multiple sclerosis, nephritis, and scleroderma, the treatments are based on pathology, not etiology. The conventional approach to autoimmune disease seeks to answer the question of WHAT disease the patient has, not WHY the patient has the disease, suggesting only small variations in treatment.

Functional medicine considers the diagnosis, of course, but also seeks to answer the question WHY. The etiology of any disease may be different in people with the same diagnosis or pathology. Conversely, the etiology may be the same in patients with very different pathologies—for example, mercury toxicity is found in both multiple sclerosis and Crohn's disease. Approaches to treatment, therefore, will vary when the upstream causes and downstream effects differ from patient to patient. Treating only the downstream effects (such as nutrient deficiencies or food sensitivities due to malabsorption and intestinal hyperpermeability) without treating the upstream causes (such as gluten sensitivity, gastrointestinal yeast, or mercury toxicity) will often result in treatment failure.

Focusing on the patient's individual etiology of autoimmune disease provides a personalized framework for diagnosis and treatment. There are 5 primary etiologic factors that affect gene expression and give rise to nearly all disease, including autoimmune disease: toxins, allergens, infections (or microbial imbalances), poor diet, and stress.

Findings and Assessment at Initial Visit

History of Present Illness

At age 56, MP presented with a 4-year diagnosis of psoriatic arthritis that was progressively worsening despite aggressive medication therapy. He experienced severe pain, decreased range of motion, and swelling in his feet, ankles, knees, and hands. He walked with a limp. His left shoulder was also frequently painful. All symptoms were worse in the morning. He had been taking etodolac (Lodine®) and methotrexate for the past 3 years, and adalimumab (Humira®) for the past 6 months. The onset of psoriatic arthritis began with the development of pain and redness in his right great toe, for which he was treated unsuccessfully with antibiotics. Shortly thereafter, he developed psoriasis behind his knees, on his feet, and behind his ears. He had psoriatic nails for most of his life.

¹ This case was assembled and edited by The Institute for Functional Medicine with the gracious support of Metametrix Clinical Laboratory and The UltraWellness Center.

Just prior to receiving the diagnosis of psoriatic arthritis, he had a left knee arthroscopy that was negative for degenerative disease but positive for synovitis. He also developed a hemorrhagic Baker's cyst, causing severe swelling and pain in his left foot and knee. MP also complained of esophageal reflux, a recent 15-pound weight gain, and intermittent depression.

Past Medical History

Migraine headaches

Disc protrusion with sciatica at L5-S1

Family Medical History

- ⊗ MP's mother is alive at age 82; she has been diagnosed with congestive heart failure, malnutrition, rheumatoid arthritis, depression, and schizophrenia.
- ⊗ MP's father died at age 62; he had cancer, obesity, and alcoholism.
- ⊗ MP's brothers have been diagnosed with cancer, inflammatory arthritis, inflammatory bowel disease, alcoholism, and depression.
- ⊗ His sisters have alcoholism, depression, and bipolar disorder.
- ⊗ The maternal grandmother died at 80; she had been diagnosed with hypertension, diabetes and depression.
- ⊗ The paternal grandmother died at 70; she had heart disease, hypertension, obesity, and diabetes.
- ⊗ The paternal grandfather died at 80; he had heart disease, hypertension, obesity, and diabetes.
- ⊗ MP's son has schizophrenia and his daughter has ADHD.

Medications and Supplements

Etodolac (Lodine) 500 mg; 1 tab PO QD

Methotrexate 2.5 mg; 6 tablets per week

Adalimumab (Humira) 40 mg/0.8 mL; 1 SQ injection every other week

Aspirin 81 mg; 1 tablet PO QD

Zolpidem (Ambien®) prn

Omega-3 EPA 1000 mg; 1 capsule PO QD

Multivitamin and mineral; 1 tablet PO QD

Past history of multiple courses of antibiotics

Social History

MP leads a stressful life with a highly demanding job as a university professor and researcher. His schedule leaves little time for relaxation, although he does meditate daily. MP is married with 2 children, including one who has been diagnosed with schizophrenia and lives at home.

Nutrition, Exercise, and Environmental Exposures

Usual Dietary Intake:

Breakfast: oatmeal with low fat milk, brown sugar

Lunch: tuna wrap or soup with cookies

Dinner: fish or meat, vegetables, potato or pasta, occasional salad with commercial salad dressing

Snacks: cookies or protein bars

MP avoids chocolate and fatty foods. He eats out more than 5 times per week. He craves sweets and caffeine. MP consumes 3-4 cups of coffee and one diet soda per day (357-464 mg caffeine). MP drinks approximately 12 alcoholic beverages per week, including wine and the occasional scotch. MP reported that his liver enzymes have been elevated, and he has some concern about his drinking.

Exercise:

MP does not engage in exercise due to his long days, but is motivated to start.

Environmental Exposures:

Many mercury amalgams

Mold exposure

Systems Review

General: 15-pound weight gain

HEENT: Sensitive to loud noises; dry eyes with crusty secretions; intolerant of cigarette smoke, perfumes, and auto exhaust; canker sores; esophageal reflux

GI: Chronic constipation

MSK: Tendonitis

M/E: Intermittent depression, difficulty concentrating, irritability

Significant Physical Exam Findings

Blood pressure 138/87 (LAS)

Height 70.5"

Weight 204 pounds

Body mass index 28.85

Waist circumference 40"

Hip circumference 43"

Waist-hip ratio 0.9

Initial Assessment and Laboratory Recommendations

Organized According to the Functional Medicine Matrix

Initial Clinical Assessment	Laboratory Tests Ordered
IMMUNE SURVEILLANCE AND INFLAMMATORY PROCESS	
Psoriatic arthritis Psoriasis Psoriatic nails Blepharitis Aphthous stomatitis	1. HLA DQ2 and DQ8 genotypes 2. Celiac panel 3. IgG food sensitivities 4. Inflammatory/autoimmune panel with Iron 5. Vitamin D 6. Omega-3 and 6 fatty acids 7. Lipid peroxides (oxidative stress marker) 8. RBC magnesium
HORMONE AND NEUROTRANSMITTER REGULATION	
Depression Family history of heart disease, hypertension, psychiatric disorders, diabetes	9. Comprehensive metabolic panel with fasting glucose & insulin, HgbA1C 10. Lipids 11. Saturated and monounsaturated fatty acids 12. Thyroid panel
DIGESTION AND ABSORPTION	
Gastroesophageal reflux disease Chronic constipation Yeast overgrowth Migraines Family history IBD	13. DNA microbial stool analysis with chemistries *HLA DQ, IgG foods, celiac panel
DETOXIFICATION AND BIOTRANSFORMATION	
Mercury toxicity (multiple amalgams)	14. Whole blood toxic metals 15. Urine toxic metals challenge test (with DMPS chelating agent)
PSYCHOLOGICAL AND SPIRITUAL EQUILIBRIUM	
High-stress work life Depression Family history of psychiatric illness	*Vitamin D, omega-3 and -6 fatty acids, thyroid panel
*Laboratory tests frequently pertain to multiple areas of imbalance, and therefore may be listed in more than one Matrix category.	

Significant Laboratory Findings

Organized According to the Functional Medicine Matrix

IMMUNE SURVEILLANCE AND INFLAMMATORY PROCESS	
Test	Results
1. DQ Genotype	Allele Detected: HLA DQA1*0501

Psoriatic arthritis is associated with celiac disease and subclinical gluten enteropathy.² HLA DQ is a heterodimer cell surface type protein found on antigen-presenting cells. There are 9 serotypes of DQ proteins. Approximately 90% of celiac patients express the DQ2 heterodimer serotype, and approximately 7% of patients express the DQ8. The DQ2 heterodimer is encoded by the DQA1*0501 and the DQB1*0201 alleles; DQ8 is encoded by the DQA1*0301 and the DQB1*0302 alleles. More than 3% of celiac patients present with half the DQ2 heterodimer. In one study looking at 1008 European celiac patients, 61 were identified who carried neither the DQ2 nor DQ8 heterodimers; 57 of these encoded half of the DQ2 heterodimer.³

MP’s test results demonstrated the presence of half the DQ2 heterodimer—specifically, the HLA DQA1*05 allele. Thus, celiac disease could not be ruled out based on this finding. HLA DQ susceptibility is carried by about 30-40% of the population, but only 1% manifest with frank celiac disease.

Test	Result	Reference Interval
2. Celiac Disease Panel		
Immunoglobulin A	438 HN	82-453 mg/dl; OR ≥10 mg/dL
Transglutaminase IgA	<20	<20 Units

IgA tissue transglutaminase antibodies (TTG) were undetectable, reducing the likelihood of celiac disease. However, antigliadin IgA and IgG antibodies may detect milder gluten intolerance. Unfortunately, though ordered, the laboratory did not perform these tests.

Test			
3. IgG (total) Reactive Foods*			
Almond (+2)	Chili Pepper (+2)	Lobster (+1)	Sesame (+1)
Amaranth (+1)	Clam (+2)	Milk, Cow's (+2)	Shrimp (+1)
Barley (+1)	Corn (+1)	Onion (+1)	Tomato (+1)
Bean, Kidney (+1)	Crab (+1)	Oyster (+2)	Wheat (+2)
Cantaloupe (+1)	Cranberry (+1)	Pineapple (+1)	Yeast, Baker's (+3)
Cashew Nut (+1)	Egg (+3)	Potato, White (+1)	Yeast, Brewer's (+4)
Cheese (+1)	Garlic (+1)	Scallops (+2)	
* Results range from 0 (no reaction) to +5 (severe reaction).			

ELISA testing for total IgG response to 90 different foods demonstrated a strong positive reaction to eggs and yeast, and mild positive reactions (+1 or +2) to 25 other foods, including gluten-containing wheat and barley. Food sensitivities generate significant inflammation, and as such are both a cause and effect of intestinal hyperpermeability.⁴⁻⁶ Other factors contributing to intestinal hyperpermeability included alcohol and NSAID use.^{7,8}

Despite the equivocal celiac panel discussed above, a gluten-free trial was suggested because of the positive IgG reaction to wheat and barley and the presence of the DQ2 allele. It was also recommended that he eliminate dairy and those foods with reactivity of +3 and above, and limit intake of the other +2 foods.

Test	Result	Reference Interval
4. Inflammatory Markers		
Iron	80	50-150 mcg/dL
Transferrin	246	201-336 mg/dL
TIBC	308	255-450 mg/dL
Iron saturation	26	20-50%
Ferritin	322 HN	23-336 ng/mL
ESR Westergren	7	0-20 mm/hr
CRP High Sensitivity	2.9 mg/L H	Relative Cardiovascular Risk: Low <1.0; Average 1.0-3.0; High 3.1-10.0
Rheumatoid Factor	<20	<30 IU/mL
ANA Screen	Negative	Negative

With the exception of a high-normal ferritin and elevated hs-CRP, none of the inflammatory markers were abnormal. Methotrexate and adalimumab (Humira) attenuate markers of inflammation, and may have been responsible for these negative findings.⁹⁻¹¹

Test	Result	Reference Interval
5. Vitamin D 25 OH	21 ng/mL L	< 20 ng/mL: Insufficiency 20-40 ng/mL: Hypovitaminosis D 40-100 ng/mL: Sufficiency > 100 ng/mL: Toxicity

The pathophysiology of psoriatic arthritis includes upregulation of Th1-driven inflammation. Vitamin D specifically regulates T-helper and dendritic cell function while inducing regulatory T-cells, causing a decrease in Th1 activity.^{12, 13} MP's low serum vitamin D level may have contributed to the severity of his symptoms. The optimal serum vitamin D range is now thought to be 40-70 ng/mL. Individuals with chronic disease should maintain levels between 55 and 70 ng/mL.¹⁴ Hypovitaminosis D may also have played a role in MP's depression.¹⁵

Test	Result uM	80% and 95% Reference Intervals
6. Plasma Omega-3 and -6 Fatty Acids		
<i>Omega-3 fatty acids:</i>		
Alpha linolenic acid (ALA)	60	>37; 22-144
Eicosapentaenoic acid (EPA)	105	>44; 19-362
Docosahexaenoic acid (DHA)	327	>172; 95-333
<i>Omega-6 fatty acids:</i>		
Arachidonic acid (AA)	739 H	330-630; 260-750

Probably because MP was supplementing them, the omega-3 fatty acids (ALA, EPA, and DHA) were all within normal limits. However, the omega-6 fatty acid AA was high normal, supporting the production of pro-inflammatory cytokines. The 2- and 4-series eicosanoids, produced from AA, stimulate the upregulation of TNF-alpha, a Th1 cytokine strongly implicated in psoriatic arthritis pathogenesis.¹⁶ MP was taking the drug adalimumab (Humira), which binds TNF-alpha directly, blocking its ability to bind certain receptors.¹⁷ Reducing AA could assist in modulating the inflammatory effects of psoriatic arthritis by reducing AA-derived eicosanoids.

MP also demonstrated signs of insulin resistance (discussed further below). It has been suggested that insulin stimulates the production of AA,¹⁸ and AA elevation has been associated with insulin resistance.^{19,20} These findings suggest a mechanistic link between psoriatic arthritis and metabolic syndrome. An elevated AA/EPA ratio has been shown to positively correlate with depression.²¹ MP had more than 7 times the amount of AA relative to EPA in his plasma, despite supplementation with omega-3 fatty acids.

Test	Result	Optimal and 95% Reference Intervals
7. Lipid Peroxides (serum)	1.6 nmol/mL H	<1.5; ≤2.0
8. Magnesium (RBC packed cells)	25 ppm L	>26; 18-40

Elevated serum lipid peroxides demonstrated oxidative stress. Sub-optimal magnesium is found in a large percentage of the population, and is a common finding in those with chronic disease.²²

<i>HORMONAL AND NEUROTRANSMITTER REGULATION</i>		
Test	Result	Reference Interval
9. Comprehensive Metabolic Panel:		
Glucose	106 H	70-99 mg/dL
Insulin	21 H	6-27 uIU/mL (ORI: 0.1-5.0) ²³
Glycohemoglobin A1C	5.5	4.4-6.8%
ALT	44 H	0-40 IU/L
10. Lipids:		
Cholesterol, Total	218 H	< 200 mg/dL
Triglycerides	431 H	< 150 mg/dL
Cholesterol, HDL	43 LN	40-59 mg/dL
Cholesterol, LDL	Not done due to interference of elevated triglycerides	< 130 mg/dL

MP's lab findings met the American Heart Association guidelines for the diagnosis of metabolic syndrome: elevated fasting blood glucose, triglycerides, and blood pressure, with low HDL.²³ The elevated ALT suggested early fatty liver disease.²⁴ A triglyceride/high-density lipoprotein ratio greater than or equal to 3.5 was suggestive of insulin resistance, and an increased likelihood of coronary artery disease.^{25, 26} A fasting insulin between 18.56 and 225 has been associated with a significantly greater risk for cardiovascular disease as compared to a fasting insulin between 0.1-5.0.²³ An association between psoriatic arthritis, dyslipidemia, hypertension, obesity, and insulin resistance has been suggested due to the shared upregulation of inflammatory pathways.²⁷

Test	Result uM	80% and 95% Reference Intervals
11. Saturated and Monounsaturated Fatty Acids		
<i>Plasma Saturated Fatty Acids:</i>		
Palmitic acid	3,408 HN	1,610-2,946; 1,364-3,525
<i>Monounsaturated Fatty Acids:</i>		
Palmitoleic acid	327 H	< 155; ≤238
Vaccenic acid	208 H	87-175; 74-209
Oleic acid	>2800 H	1,079-2,733; 1,079-2,800

Elevated saturated and monounsaturated fatty acids represent a pattern seen in metabolic syndrome with hypertriglyceridemia, where insulin stimulates the liver enzyme fatty acid synthase to produce saturated fatty acids. Insulin also stimulates delta-9 desaturase, which converts saturated to monounsaturated fatty acids, primarily palmitoleic, vaccenic, and oleic.²⁸

Test	Result	Reference Interval
12. Thyroid Panel		
TSH	2.39 HN	0.28-3.89 mIU/L
T4, Free	0.58 LN	0.58-1.64 ng/dL
T3, Free	2.9 LN	2.5-3.9 pg/mL
Thyroglobulin Ab	< 20	< 40 IU/mL
Thyroid Peroxidase Ab	< 20	<35 IU/mL

MP's thyroid panel was within normal limits, including antibodies. Optimal TSH is now considered to be 2.5, but may be as low as 1.18 mIU/L.²⁹ Free T3 and free T4 were low normal. These results suggested that the thyroid should be monitored, particularly given the association of hypothyroidism with rheumatologic conditions. Nutrients involved with thyroid function, including red blood cell zinc, whole blood selenium, and plasma tyrosine, were within normal limits.

DIGESTION AND ABSORPTION	
Test	Results
13. DNA microbial stool profile	
Candida sp.	+3 ≥10,000 pg DNA/g specimen H

As suspected, DNA stool analysis demonstrated a significant quantity of Candida species in the gastrointestinal tract. Candida species in particular have been found in significant amounts relative to controls in the saliva, skin, and stool of psoriatic patients.³⁰

DETOXIFICATION AND BIOTRANSFORMATION
Given MP's high number of amalgams, there was concern about mercury. According to the CDC, up to 75% of an individual's mercury exposure may be released from amalgams. ³¹ Whole blood toxic metals (Test #14) were within normal limits, ruling out significant current release from amalgams. A DMPS-challenged urine toxic element test (Test #15) was also ordered to assess body burden, but MP had not completed the test at the time of this publication.

Summary of Initial Assessments, Laboratory Findings, Treatments, and Treatment Rationale

Organized According to the Functional Medicine Matrix*

IMMUNE SURVEILLANCE AND INFLAMMATORY PROCESS			
Clinical Assessment and Diagnoses	Laboratory Results	Recommended Treatment	Treatment Rationale
• Gluten sensitivity • Intestinal hyperpermeability • Multiple IgG food sensitivities • Hypovitaminosis D • Psoriatic arthritis • Psoriasis • Psoriatic nails • Blepharitis • Aphthous stomatitis • Family history of autoimmunity	• + celiac gene (HLA DQ2) • + IgG to 27 foods • Low serum vitamin D • Elevated plasma arachidonic acid • Elevated serum lipid peroxides • Low RBC magnesium	• Anti-inflammatory medicinal food; 2 scoops QD • EPA/DHA 6:1; 1 cap BID • Vitamin D3 5000IU; 2 caps QD Dietary changes: • 100% gluten and dairy free. • Avoid yeast and eggs. • Eat whole, low glycemic index foods, good fats, and protein. • Discontinue alcohol, caffeine, sugar.	• Intended to reduce GI inflammation and intestinal permeability • Anti-inflammatory omega-3 fatty acids used to minimize pro-inflammatory events supported by high arachidonic acid • Serum vitamin D goal: 55-70 ng/mL • Dietary changes are based on clinical history, IgG food sensitivities, HLA DQ2 status, elevated metabolic markers, and GI yeast overgrowth *Also supportive: probiotics and multivitamin and mineral

HORMONE AND NEUROTRANSMITTER REGULATION			
Clinical Assessment and Diagnoses	Laboratory Results	Recommended Treatment	Treatment Rationale
• Metabolic syndrome • Suspected fatty liver • Subclinical hypothyroidism • Migraine headaches • Depression • Family history of heart disease, hypertension, psychiatric disorders, diabetes	• Elevated triglycerides • Elevated blood glucose • High insulin • Elevated total cholesterol • Low-normal HDL • Elevated ALT • High-normal TSH; low-normal free T3 and free T4	• Methyl donors (B12, folic acid, and B6); 1 cap BID • Amino acids (taurine, glycine, N-acetyl-cysteine, methionine); 3 caps BID • High-dose multivitamin and mineral without iron; 4 tabs BID • Dietary changes as noted under <i>Immune Surveillance and Inflammatory Process</i> (above)	• Methyl donors may be effective for both methylation and sulfuration activity. As such, they are beneficial for mood, cardiovascular and hepatic health • These amino acids support hepatic function, are neuroactive, and may be anxiolytic. • High-dose multivitamin/mineral is used for general micronutrient (cofactor/coenzyme) support • A low glycemic index diet with good sources of fatty acids and proteins is imperative for metabolic issues *Also supportive: EPA/DHA; vitamin D

<i>DIGESTION AND ABSORPTION</i>			
Clinical Assessment and Diagnoses	Laboratory Results	Recommended Treatment	Treatment Rationale
• Gastroesophageal reflux disease • Chronic constipation • GI yeast overgrowth • Family history IBD	• DNA stool analysis: +3 Candida sp.	• 450 billion CFU probiotic; 1 packet BID • Fluconazole 100 mg; 1 tab QD x 30 days	• High-dose probiotic therapy supports a healthy microbiota and is beneficial for treatment of autoimmunity, intestinal hyperpermeability, food sensitivities, constipation, GI yeast, and parasitic infections • Yeast overgrowth has been associated with psoriatic arthritis and antibiotic use. Clinical experience dictates long-term fluconazole with dietary changes for best outcome

DETOXIFICATION AND BIOTRANSFORMATION			
Clinical Assessment and Diagnoses	Laboratory Results	Recommended Treatment	Treatment Rationale
Mercury toxicity (multiple amalgams)	- Negative whole blood toxic metals - Urine toxic metals (MP did not complete this test)	- Methyl donors; 1 cap BID - Amino acids (taurine, glycine, N-acetyl-cysteine, and methionine); 3 caps BID - High-dose multivitamin and mineral without iron; 4 tabs BID	- The blood toxic metals assay was negative, ruling out current exposure. However, there was concern about a mercury body burden from past exposure - Methyl donors and amino acids are helpful in supporting hepatic detoxification of toxic metals - The multivitamin and mineral formula supports detoxification/ antioxidant enzymes by providing cofactor and coenzyme nutrients

<i>PSYCHOLOGICAL AND SPIRITUAL EQUILIBRIUM</i>			
Clinical Assessment and Diagnoses	Laboratory Results	Recommended Treatment	Treatment Rationale
• High-stress work life • Depression • Family history of psychiatric illness	• Low serum vitamin D • Elevated plasma arachidonic acid • High-normal TSH • Low-normal free T3 and free T4	• Continue daily meditation practice • Vitamin D3 5000IU; 2 caps QD • EPA/DHA 6:1; 1 cap BID • Dietary changes as noted under Immune Surveillance and Inflammatory Process (above) • Methyl donors (B12, folic acid, and B6); 1 cap BID • Amino acids (taurine, glycine, N-acetyl-cysteine, methionine); 3 caps BID • High-dose multivitamin and mineral without iron; 4 tabs BID	• Meditation improves general well-being and reduces stress, inflammation, and depression • Hypovitaminosis D and an elevated plasma AA/EPA ratio have been associated with depression • Removing antigenic, inflammatory foods (and alcohol, caffeine, and sugar) supports psychological equilibrium • Methyl donors may be effective for both methylation and sulfuration activity; hence, they are beneficial for mood, cardiovascular and hepatic health • These amino acids support hepatic function, are neuroactive, and may be anxiolytic • High-dose multivitamin/mineral is used for general micronutrient (cofactor/coenzyme) support
*Assessments, laboratory tests and treatments frequently pertain to multiple areas of imbalance and may therefore be listed in more than one Matrix category.			

Follow-up Visit at Five Months

MP arrived pain-free the day of the 5-month follow-up visit, stating he hadn't felt so good in years. On average, he reported an 80% reduction in pain with improved mobility. He could climb stairs more quickly and was no longer limping. Morning pain and stiffness were gone. Previously, his hands were swollen and difficult to open. Now, the swelling was resolved and movement was normal. MP had not used any nonsteroidal anti-inflammatories or adalimumab for 2 months. He reduced methotrexate from 15 to 5 mg per week.

His reflux and migraines were gone. His mood had improved and he was less irritable. He was no longer constipated. He reported having a single, well-formed bowel movement daily. He was still under a great deal of stress, working 80 hours a week, but meditation continued to be helpful. He reported he was still getting occasional canker sores.

He quit caffeine and reduced alcohol intake considerably. He started on hypoallergenic prepared meals, which were perfect for his busy lifestyle, enabling him to follow the dietary suggestions. He was taking his supplements regularly. He was losing weight, his clothes fit much better, and he was satisfied with his dietary changes. Overall, he was very pleased with his progress.

The RD/Nutritionist's Comments

Because of his busy lifestyle, the prepared, low glycemic index, hypoallergenic (gluten-, dairy-, and yeast-free), whole-foods meals were a nice match for MP. Indeed, he experienced the greatest symptom relief when he began eating these meals as his primary food source. The dietary changes addressed his metabolic syndrome and provided a good balance of macro- and micronutrients, including vitamins, minerals, protein, and unsaturated fatty acids.

When he reintroduced gluten-containing foods some months later, there was a strong recurrence of arthritic pain and fatigue. It appeared to MP that gluten was a major trigger for his arthritis, which is interesting because the laboratory findings showed eggs and yeast to be the most antigenic foods. MP was counseled on dining out gluten-free since he ate out regularly.

MP was encouraged to eat whole foods high in the nutrients that he was deficient in, so as to minimize long-term dependence on multiple supplements. For example, nuts, legumes, gluten-free whole grains such as buckwheat, and dark leafy greens are high in magnesium; salmon and sardines are good sources of vitamin D (in addition to sunlight). He was given resources to gradually expand his nutritional portfolio with whole-foods recipes and simple-to-prepare menus. MP was also educated to minimize exposure to factors that contribute to intestinal hyperpermeability, including alcohol and NSAIDs.

Significant physical exam findings on follow-up:

Blood pressure 118/73 LAS (5 months ago: 138/87)

Pulse 58 BPM

Weight 200 pounds (5 months ago: 204)

Case Summary

In this particular patient (MP), gluten sensitivity and yeast overgrowth were the proximal etiologies, with multiple downstream effects including increased intestinal permeability, nutrient malabsorption and deficiency, constipation, GERD, canker sores, blepharitis, psoriasis, and metabolic syndrome (triggered by inflammatory factors). Psoriatic arthritis and psoriasis are often caused by gluten and/or other food sensitivities, yeast overgrowth, or mercury toxicity. These may all serve as triggers for a chronic inflammatory disease and they all need to be addressed in the assessment and treatment. Treating upstream causes and addressing downstream effects is necessary for all chronic illness, especially autoimmune diseases.

Removing gluten, other sensitive foods, and harmful microbes, while replacing missing nutrients and providing compounds to facilitate gut healing, were the core components of this patient's therapy. His unique needs were identified and treated in a personalized approach that models the diagnostic and therapeutic framework for treatment of nearly all chronic diseases using the matrix of functional medicine.

Additional Forms

- ⊗ A completed Matrix form for MP is provided in Figure 1.
- ⊗ A convenient case-at-a-glance summary for MP is provided in Figure 2.

Figure 1:
Completed Matrix Form for MP

Case at a Glance: Psoriatic Arthritis

History of Present Illness

MP was 56 when he presented to the clinic with psoriatic arthritis. Over the previous year, his symptoms had progressively worsened, with increased pain, decreased range of motion, and swelling in his feet, ankles, hands, and knees. He walked with a limp and had difficulty climbing stairs. His left shoulder was also frequently painful. He was taking etodolac (Lodine®), methotrexate, and adalimumab (Humira®), which did not adequately control his symptoms. He maintained a highly demanding career as a university professor and researcher. He drank alcohol and caffeinated beverages regularly. He meditated 15 minutes each morning. He had a positive family history for rheumatoid arthritis, sero-negative inflammatory arthritis, schizophrenia, and inflammatory bowel disease.

Abbreviated Assessments, Laboratory Findings, and Treatments Organized According to the Functional Medicine Matrix (Refer to full case presentation for details, including treatment rationale.)

Clinical Assessment	Laboratory results	Recommended Treatment
IMMUNE SURVEILLANCE AND INFLAMMATORY PROCESS		
Gluten sensitivity Intestinal hyperpermeability Multiple IgG food sensitivities Hypovitaminosis D Psoriatic arthritis, nails, skin Blepharitis, aphthous stomatitis FMH: autoimmunity	+ celiac gene (HLA DQ2) +IgG to 27 foods Low vitamin D & magnesium Elevated arachidonic acid & lipid peroxides	Anti-inflammatory medicinal food EPA/DHA Vitamin D3 Dietary changes: Gluten and dairy free. Avoid yeast and eggs. Eat whole, low glycemic foods, good fats & protein. D/C alcohol, caffeine, sugar.
HORMONE AND NEUROTRANSMITTER REGULATION		
Metabolic syndrome Suspected fatty liver Subclinical hypothyroidism Migraine headaches FMH: HD, DM, HTN, psychiatric disorders	Elevated triglycerides, FBS, insulin, cholesterol Low-normal HDL Elevated ALT High normal TSH	Methyl donors (B12, folic acid, and B6) Amino acids (taurine, glycine, N-acetyl-cysteine, methionine) High-dose multivitamin and mineral without iron Dietary changes as noted above
DIGESTION AND ABSORPTION		
GERD Chronic Constipation GI yeast overgrowth Family history IBD	DNA stool analysis: +3 Candida sp.	450 billion CFU probiotic Fluconazole 100 mg; 1 tab QD x 30 days
DETOXIFICATION AND BIOTRANSFORMATION		
Mercury toxicity (multiple amalgams)	Negative whole blood toxic metals Urine toxic metals challenge test not completed	Methyl donors (B12, folic acid, and B6) Amino acids as noted above High-dose multivitamin and mineral without iron
PSYCHOLOGICAL AND SPIRITUAL EQUILIBRIUM		
High-stress work life Depression Family history of psychiatric illness	Low serum vitamin D Elevated arachidonic acid High-normal TSH Low-normal free T3 and free T4	Continue daily meditation practice Vitamin D3 5000IU EPA/DHA Dietary changes as noted above Methyl donors (B12, folic acid, and B6) Amino acids as noted above High-dose multivitamin and mineral without iron

5-Month Follow-up:

MP was markedly improved, stating that he hadn't felt so good in years. He reported an 80% reduction in overall pain, with improved mobility and decreased swelling. He was able to walk upstairs and his limp was gone. Morning pain and stiffness were gone. He had not used adalimumab (Humira) for two months and reduced methotrexate from 15 to 5 mg per week. He was following the dietary recommendations and taking the supplements. He eliminated caffeine and reduced alcohol intake considerably. Reflux and migraines were gone. His mood improved, and he was less irritable. He lost weight. He was no longer constipated. He was still under a great deal of stress, working 80 hours a week, but meditation continued to be helpful.

FUNCTIONAL MEDICINE CASE: ATTENTION DEFICIT HYPERACTIVITY DISORDER (ADHD)¹

Kara N. Fitzgerald, ND, and Mark Hyman, MD

Findings and Assessment at Initial Visit

History of Present Illness

LC, 12 years old, presented with attention deficit hyperactivity disorder (ADHD), dysgraphia, environmental allergies, asthma, insomnia, eczema, canker sores, migraine headaches, muscle cramps, stomach pain, nausea and diarrhea. He was first diagnosed with ADHD at age 5. He repeated kindergarten because of attention and behavioral difficulties. He began methylphenidate (Ritalin®) in first grade and continued to take it through fourth grade, although it did not change his behavior significantly. The drug was discontinued in fourth grade due to growth retardation. Off the medication, he gained weight but also increased his intake of junk food and deli meats.

LC had never received a positive teacher's report. Off the methylphenidate, he continued to be disruptive and unfocused. He excelled in math but had severe dysgraphia (Figure 1). (Dysgraphia is defined as illegible handwriting and spelling errors and is associated with ADHD.¹) LC's environmental allergy symptoms were sinus congestion, postnasal drip, sore throats, and hives, for which he took cetirizine (Zyrtec®). His mother had removed his bedroom carpet and installed hardwood floors, but there was minimal improvement in his symptoms after these changes. His mother noted that dairy worsened his sinus congestion and postnasal drip. LC usually developed full-blown sinusitis about twice a year, for which he was prescribed antibiotics.

As a toddler, LC had developed asthma, hyperkeratosis pilaris, and eczema. For the asthma, LC was maintained on albuterol, levalbuterol (Xopenex®) and flunisolide (AeroBid®). The asthma caused difficulty with breathing at night, and therefore he did not sleep well. LC also suffered with cold-induced asthma attacks. His skin and anus were frequently itchy, and he got frequent canker sores in his mouth.

LC suffered from migraine headaches with hypersensitivity to light and sound, and had muscle cramps and spasms. For these complaints, he was given acetaminophen and ibuprofen. His stomach pain was treated with cimetidine. He also complained of nausea and had frequent bouts of diarrhea.

Comment: In most realms of psychiatry all the physical problems covered in LC's HPI are considered irrelevant in guiding diagnosis and therapy of brain disorders or ADHD. In looking at his case from a functional perspective, however, they are the most relevant findings in his history and provide clear treatment direction.

Past Medical History

Birth and Infancy:

LC was a healthy seven lb, 10 oz baby, but the vaginal delivery was difficult. He was treated for hyperbilirubinemia. LC was breastfed for 10 months, and then he was given soy formula due to a "sensitive stomach." Gluten-containing grains were introduced before one year of age. He was prone to diaper rash, had sensitive skin, and received frequent antibiotics for otitis media as a toddler.

¹ This case was assembled and edited by The Institute for Functional Medicine with the gracious support of Metametrix Clinical Laboratory and The UltraWellness Center.

Comment: When introduced into the diet prior to the age of one, gluten-containing grains are associated with a statistically significant increase in the incidence of celiac disease in susceptible patients.² Further, the use of soy formula in infants with a first degree relative with allergies may be associated with increased incidence of allergies, food intolerances and eczema.³ Early antibiotic use is also associated with increased incidence of atopic conditions, including asthma.⁴⁻⁷

Immunizations:

LC received a full vaccine schedule, including annual influenza shots.

Trauma:

LC sustained a concussion at 5 years old, but the CAT scan was normal.

Family Medical History

LC's mother had migraine headaches, sinusitis, and food allergies. His sister had environmental allergies. LC's father was in good health.

Medications

Cetirizine (Zyrtec)

Albuterol

Levalbuterol Inhaler (Xopenex)

Flunisolide (Nasarel)

Cimetidine (Tagamet®)

Acetaminophen

Ibuprofen

Comment: This is an overwhelming pharmacopoeia for a 12-year-old boy, and his physical, mental, and behavioral symptoms still were not under control. Even the methylphenidate did not significantly help his school performance or behavior or “cure” his ADHD, although it did cause growth retardation, and was therefore discontinued. Side effects of his other medications may also have been involved in the pathogenesis of his complaints. For example, cimetidine has been associated with nutritional deficiencies and gastrointestinal bacterial overgrowth from gastric acid inhibition.⁸ Glutathione depletion results from acetaminophen use⁹; and intestinal permeability increases with use of nonsteroidal anti-inflammatory medications such as ibuprofen.¹⁰ Flunisolide has also been shown to inhibit growth in children.¹

Nutrition and Environmental Exposures

Usual Dietary Intake:

Breakfast: eggs and bacon, cereals with soy milk, occasional fruit

Lunch: deli meat sandwiches, cookies, peanut butter and crackers, carrots, and lemonade

Dinner: pizza, pork or chicken, broccoli, green beans, and rice/pasta/potatoes

LC had strong sugar and pasta cravings. He ate candy, cookies, or ice cream on a daily basis, although he felt better when he avoided dairy.

Environmental Exposures:

LC's house had an unaddressed mold infestation. The type of mold was unknown. LC had no known drug allergies, but had numerous environmental allergies, including tree pollen and mold.

Initial Assessment and Laboratory Recommendations

Organized According to the Functional Medicine Matrix

Initial Clinical Assessment	Laboratory Tests Ordered
LIFESTYLE FACTORS: NUTRIENT IMBALANCES	
Nutrient-poor diet Muscle spasms Audio sensitivity Hyperkeratosis pilaris Anxiety ADHD	1. RBC essential minerals 2. Serum vitamins A, E, & beta carotene 3. Serum fatty acids 4. Organic acid B vitamin markers
IMMUNE SURVEILLANCE AND INFLAMMATORY PROCESS	
ADHD Asthma Allergies Headaches Hives Sinusitis Atopic dermatitis Aphthous stomatitis PMH: diaper rash, otitis media FMH: food and environmental allergies, migraine headaches, sinusitis	5. Vitamin D 6. IgG food sensitivities 7. Celiac panel
DIGESTION AND ABSORPTION	
GERD IBS Pruritus ani > GI yeast infection Nausea Frequent antibiotic use ADHD	8. Complete blood count and metabolic panel (assesses yeast or parasite infection) 9. Organic acids microbial markers * IgG food sensitivities, celiac panel
DETOXIFICATION AND BIOTRANSFORMATION	
ADHD Food additives	10. 6-hour urine toxic metal challenge test with 250 mg DMPS (2,3-dimercapto-1-propane-sulphonic acid) provocation
HORMONE AND NEUROTRANSMITTER REGULATION	
ADHD Dysgraphia Insomnia Anxiety	11. Plasma amino acids 12. Urine neurotransmitter metabolites
*Laboratory tests frequently pertain to multiple areas of imbalance, and therefore may be listed in more than one Matrix category.	

Significant Laboratory Findings

Organized According to the Functional Medicine Matrix

LIFESTYLE FACTORS: NUTRITIONAL IMBALANCES			
Test	Results		95% Reference Interval
1. Red Blood Cell Minerals			
Zinc	2.5	L	3.3-7.7 ppm
Magnesium	15	L	18-40 ppm
Copper	260	LN	257-500 ppb
Manganese	22	LN	19-41ppb
Chromium	1.7	LN	1.4-7.9 ppb

LC was very low in zinc and magnesium; low-normal levels were reported for the rest of the minerals. These findings were not surprising given LC’s poor diet, GI inflammation, and cimetidine use. Zinc deficiency is implicated in asthma, atopic dermatitis, allergies, and ADHD.¹²⁻¹⁴ Magnesium deficiency is also implicated in headaches, insomnia, muscle cramps, and spasms.¹⁵ Copper and manganese are important cofactors in the antioxidant enzyme superoxide dismutase. Chromium as chromodulin may improve cellular glucose uptake by potentiating insulin receptor activity.¹⁶

Test	Results mg/L		95% Reference Interval
2. Serum Vitamins			
Vitamin E	7.2	LN	7.1-31.0
Vitamin A	0.55	LN	0.41-1.5
Beta-carotene	<0.2	L	0.22-2.7

Fat-soluble vitamins were found to be low (vitamins E and A) or undetectable (beta carotene) in LC’s serum, including vitamin D (discussed below). While sometimes such a pattern can indicate fat malabsorption, in LC’s case this was most likely due to poor dietary habits.

Test	Results uM	80% and 95% Reference Intervals
3. Serum Fatty Acids		
<i>Plasma saturated fatty acids:</i>		
Palmitic	3,425 HN	1,610-2,946; 1,364-3,525
Stearic	951 HN	546-851; 501-1,007
Arachidic	23.0 H	11.3-19.9; 9.7-22.8
Behenic	84 H	31-57; 27-66
Lignoceric	53 H	24-45; 20-52
<i>Plasma trans fatty acids:</i>		
Palmitelaidic	14.5 HN	≤10.8; ≤18.6
Total C:18 Trans	199 HN	≤107; ≤210
<i>Plasma omega-3 fatty acids:</i>		
Alpha Linolenic Acid (ALA)	60	>37; 22-144
Eicosapentaenoic Acid (EPA)	100	>44; 19-362
Docosahexaenoic Acid (DHA)	60	>46; 31-112
<i>Omega-6 fatty acids:</i>		
Arachidonic Acid (AA)	785 H	330-630; 260-750

Plasma free fatty acids (primarily palmitic acid) roughly approximate plasma triglyceride levels.¹⁷ The numerous high-normal saturated fatty acids indicated that, at 12 years old, LC probably had higher triglycerides as well, most likely caused by insulin-stimulated upregulation of liver fatty acid synthesis. Given LC's high-sugar diet, early onset dysinsulinemia was not surprising. As discussed above, mild chromium deficiency could be another underlying factor contributing to dysinsulinemia.

The elevated *trans* fatty acids (TFAs) were further evidence of LC's poor food choices. TFAs are strongly implicated in metabolic syndrome and cardiovascular disease.¹⁸

Of the polyunsaturated omega fatty acids, the inflammatory eicosanoid precursor arachidonic acid (AA) was very elevated. It was found in much greater quantity than the anti-inflammatory omega-3 fatty acid eicosapentaenoic acid (EPA), creating a relative deficiency of EPA. AA is implicated in the pathogenesis of allergies and asthma,^{19,20} while EPA insufficiency and a low EPA/AA ratio are implicated in ADHD.^{21,22}

Comment: Had LC continued with his presenting diet and lifestyle, the plasma fatty acid analysis reveals the likelihood for continued inflammatory conditions as an adult, including possibly heart disease, diabetes, and cancer. Addressing these findings early not only treated his initial complaints, but significantly reduced his risk for a future of ill health.

Test	Results ug/mg creatinine	80% and 95% Reference Intervals
4. Urinary Organic Acids		
Kynurenate	3.0 HN	≤2.9; ≤4.7
Xanthurenate	0.9 HN	≤0.90; ≤1.50

When elevated, the organic acids above demonstrate a functional B6 insufficiency.²³ A number of LC's symptoms may have been attributable to insufficient B6, including ADHD, mood disturbances, and insomnia.²⁴

IMMUNE SURVEILLANCE AND INFLAMMATORY PROCESS		
Test	Result	Reference Intervals
5. Serum Vitamin D 25 OH	24 ng/m L	< 20 ng/mL: Insufficiency 20-40 ng/mL: Hypovitaminosis 40-100 ng/mL: Sufficiency > 100 ng/mL: Toxicity

Hypovitaminosis D likely played a role in LC's imbalanced immune response, contributing to both his chronic infections and hypersensitivities. Low vitamin D has been implicated in asthma, general development problems, and mood disorders.²⁵ Optimal serum vitamin D is now thought to be between 40-70 ng/mL; individuals with serious diseases should maintain levels between 55-70 ng/mL.²⁶

Test	
6. IgG (total) Reactive Foods*	
Bean, Kidney (+1)	Cheese (+1)
Milk, Cow's (+4)	Mustard (+1)
Peanut (+4)	R. Seed (Canola) (+1)
Walnut (+1)	Yeast, Brewer's (+2)
* Results range from 0 = no reaction to +5 = severe reaction.	

ELISA testing for IgG response to 90 different foods demonstrated a strong positive reaction to dairy and peanuts, and mild positive reactions (+1 or +2) to six other foods, indicating intestinal hyperpermeability and GI inflammation.²⁷⁻²⁹ These sensitivities may be associated with the pathogenesis of atopic dermatitis, asthma, and ADHD.³⁰⁻³²

Test	Result	95 % Reference Interval
7. IgG Antigliadin	17 HN	0-19 units

LC's IgG antigliadin antibodies were trending high at 17 units. Clinical experience warranted minimizing gluten intake.

DIGESTION AND ABSORPTION

Test #8: Complete Blood Count and Metabolic Panel

LC's serum chemistries and complete blood count were within normal limits, although his lymphocyte count was higher than his neutrophil count. Clinical experience suggested that this finding, when combined with his history of antibiotic use and complaint of anal itching, probably indicated a fungal or viral infection.

Test #9: Organic Acid Microbial Markers

Surprisingly, LC's organic acid microbial markers were within normal limits, ruling against significant GI dysbiosis, although he did demonstrate intestinal hyperpermeability with multiple food sensitivities, as discussed above in "Immune Surveillance and Inflammatory Process."

DETOXIFICATION AND BIOTRANSFORMATION

Test	Result ug/g creatinine	95% Reference Interval
10. Urine Toxic Metals (6-hour challenge test)		
Lead	17 H	≤5

DMPS (2,3-dimercapto-1-propanesulfonic acid) provocation challenge demonstrated an elevated urine lead level in LC. While whole blood is considered the gold standard for identifying lead toxicity, urinary lead concentration has also been shown to increase with toxicity.³³ Chelating agents have been shown to accelerate the urinary excretion of lead and therefore may be useful for revealing lead exposure. Lead exposure may produce cognitive deficits at levels commonly encountered in blood, and therefore numerous recommendations have been made to reduce safe threshold levels.³⁴ Lead toxicity and environmental toxins such as household mold have been linked to cognitive and behavioral problems in children, including ADHD.³⁵⁻³⁸ Sources of lead include toys, paint, contaminated soil, lead plumbing, and glazed pottery.³⁴ Since essential mineral deficiencies may allow for increased uptake of toxic metals,³⁹ repletion prior to and during treatment of toxicity is important.

<i>HORMONAL AND NEUROTRANSMITTER REGULATION</i>		
Test	Result	80% and 95% Reference Intervals
11. Plasma Amino Acids		
Tryptophan	36 LN	>40; 26-62

Test	Result ug/mg creatinine	80% and 95% Reference Intervals
12. Urine Neurotransmitter Metabolites		
Homovanillate	3.0 LN	3.2-16.7; 1.0-23.0
5-Hydroxyindoleacetate	2.6 LN	2.7-14.0 1.2-39.0

The urinary neurotransmitter metabolites for dopamine and serotonin, homovanillate (HVA) and 5-hydroxyindoleacetate (5-HIAA), were low normal in LC, suggesting lower total body neurotransmitter turnover. Corroborative evidence for the risk of serotonin insufficiency was found with low plasma tryptophan, the amino acid precursor to serotonin. Furthermore, 2 important nutrients involved in dopamine and serotonin synthesis, B6 and magnesium, were both reported insufficient in LC (discussed above in “Lifestyle Factors: Nutritional Imbalances”). Genetic and metabolic research has linked imbalances of CNS dopamine and serotonin to ADHD with regard to uptake, synthesis, and breakdown, although there has not been a consistent pattern noted.⁴⁰ Serotonin imbalance has also been implicated in insomnia⁴¹ and IBS.⁴²

Summary of Initial Assessments, Laboratory Findings, Treatments, and Treatment Rationale

Organized According to the Functional Medicine Matrix

LIFESTYLE FACTORS: NUTRIENT IMBALANCES			
Clinical Assessment and Diagnoses	Laboratory Results	Recommended Treatment	Treatment Rationale
- Nutrient deficiencies - Fatty acid imbalance - Anxiety - Muscle spasms - Audio sensitivity - Hyperkeratosis pilaris	- Low RBC essential minerals - Low serum vitamins A, E, and beta carotene - Elevated plasma AA:EPA ratio - Low B6 (organic acid functional markers) - Elevated plasma saturated and <i>trans</i> fatty acids	- Zinc citrate 20 mg; 1 tab QD - Magnesium glycinate 120 mg; 2 caps QHS - Multivitamin/mineral (MVM); 2 tabs QD - EPA/DHA 6:1; 1 cap BID - Pyridoxal 5' phosphate (activated B6) 50 mg; 1 cap QD - Dietary changes as noted in "Immune Surveillance and Inflammatory Process" below	- MVM for general nutrient needs with extra zinc for immune dysfunction, diarrhea and allergies, and magnesium for muscle cramps, insomnia, anxiety, and auto sensitivity. - Anti-inflammatory omega-3 fatty acid used to minimize pro-inflammatory arachidonic acid cascade as seen clinically with asthma, allergies, dermatitis hyperkeratosis pilaris - B6: evidence supports its use in ADHD, serotonin metabolism, and methylation/sulfuration

IMMUNE SURVEILLANCE AND INFLAMMATORY PROCESS			
Clinical Assessment and Diagnoses	Laboratory Results	Recommended Treatment	Treatment Rationale
• Hypovitaminosis D • Multiple food sensitivities • Intestinal hyperpermeability • ADHD • Asthma • Allergies • Headache • Hives • Sinusitis • Atopic dermatitis • Aphthous stomatitis • PMH: diaper rash, otitis media • FMH: food and environmental allergies, migraine headaches, sinusitis	• Low serum vitamin D • Multiple + IgG food sensitivities • Elevated IgG antigliadin antibodies	• Vitamin D3 1000 U; 1 cap QD • Diet: Modified elimination diet based on test results. No dairy, peanuts, gluten, sugar, or <i>trans</i> fatty acids. Reduce saturated fat intake. Whole foods, minimally processed; organic diet. Organic dark chocolate is fine. (See also Nutritionist Comments below.)	• Serum vitamin D goal: 40-70 ng/mL • Dietary changes based on clinical history, IgG food sensitivities, antigliadin antibodies, intestinal hyperpermeability, fatty acid deficiency, and suspected fungal overgrowth *Also supportive: zinc, magnesium, probiotics

<i>DIGESTION AND ABSORPTION</i>			
Clinical Assessment and Diagnoses	Laboratory Results	Recommended Treatment	Treatment Rationale
• Yeast overgrowth • GERD • IBS • Pruritus ani • Intestinal hyperpermeability • Nausea	• Elevated lymphocyte: neutrophil ratio * +IgG food sensitivities, IgG antigliadin antibodies	• Fluconazole 100 mg; 1 tab QD x 30 days • Broad spectrum probiotics; 2 caps Q AM	• Clinical and laboratory evidence for Candida overgrowth. Clinical experience suggests long-term fluconazole with dietary changes for best outcome • Probiotic therapy to support microbiota. Beneficial for treatment of intestinal hyperpermeability and immune hypersensitivity, food sensitivities, and IBS

DETOXIFICATION AND BIOTRANSFORMATION			
Clinical Assessment and Diagnoses	Laboratory Results	Recommended Treatment	Treatment Rationale
- Mild lead toxicity - ADHD - Food additives	Elevated 6-hour urine lead after 250 mg DMPS (2,3-dimercapto-1-propane-sulphonic acid) provocation	- After 2 months on treatment protocol: Start DMSA (dimercaptosuccinic acid) 100 mg, one twice a day, every other week for 3 days (such as MTW), then 11 days off. Do this for 6 months and then repeat the DMPS challenge test - Dietary changes as noted in <i>Immune Surveillance and Inflammatory Process</i> (above)	Oral chelation with DMSA is one of the main treatments for lead toxicity. Pulse dosing DMSA and concurrent detoxification and essential minerals supplementation will minimize adverse reactions. It is important to ensure normal kidney function and bowel movements and treat nutrient deficiencies first, particularly essential minerals, amino acid deficiencies, and impaired methylation

<i>HORMONE AND NEUROTRANSMITTER REGULATION</i>			
Clinical Assessment and Diagnoses	Laboratory Results	Recommended Treatment	Treatment Rationale
• ADHD • Dysgraphia • Insomnia	• Low-normal plasma tryptophan • Low-normal urine HVA, 5HIAA	• 5HTP 50-100 mg QHS as needed for sleep	• 5HTP is a serotonin precursor. It will provide substrate for serotonin production while preserving tryptophan. CNS serotonin is methylated to produce melatonin. Increased serotonin may therefore help with insomnia
*Assessments, laboratory tests, and treatments frequently pertain to multiple areas of imbalance and may therefore be listed in more than one Matrix category.			

Follow-up Visit at Two Months

After starting his treatment, which included removing yeast and antigenic foods and adding the needed micronutrients and probiotics, LC's mother stated that he was much less disruptive in the classroom. He was sleeping through the night. His headaches and runny nose improved. He hadn't required cetirizine or flunisolide for some time. His asthma symptoms improved and were no longer triggered by cold. Light, sound, and smell sensitivities were reduced considerably. LC tolerated supplements and diet changes well, because he felt so much better when he followed the plan. No changes were made to LC's treatment plan at his 2-month visit.

Follow-up Visit at Six Months

LC's mother reported that he was free from his chronic symptoms for the first time in his life. His dysgraphia improved considerably (see Figures 1 and 2 for the pre- and post-treatment writing samples). He no longer required his medications, including antihistamines (cetirizine and cimetidine), bronchodilators, steroid inhaler, acetaminophen, and ibuprofen. His mood and behavior had stabilized, and his ability to focus improved greatly. His hyperactivity symptoms, including disruptiveness, irritability, and anxiety, were gone. His hives, asthma, runny nose and postnasal drip, anal itching, stomach aches, nausea, diarrhea, headaches, muscle cramps, and sensitivity to loud noises were all completely resolved. He slept soundly at night. He was doing well in school, academically and socially.

Just after his 6-month follow-up, LC's mother wrote the following:

We had a meeting at LC's school this morning, where the teachers, school counselor, parents, and principal all get together to review "the plan" for kids with special educational needs (in LC's case prompted by the ADHD diagnosis). This was the first time in his entire schooling history that everything seems to be going well. The input from his teachers was that he is "a different kid" than they saw in the first half of the year and that they're amazed by the difference. The school nurse hasn't seen him [in months] (and he used to be in her office several times a week). The school psychologist said his social skills are very good, age appropriate, and that she sees no problems at all. She also noted that LC seems very proud of himself and his new health and that he's taking good ownership of all the changes in his diet. He even seems to be shrugging it off when the other kids at school tell him he's an "alien" because he doesn't drink soda.

This was just such a fantastic meeting and I wanted to pass along the good news and say Thank You!

Laboratory Tests:

Follow-up testing revealed normalization of the lymphocyte:neutrophil ratio and improvement in his nutritional status, including normalized levels of vitamin E and beta carotene, RBC minerals, and tryptophan. His saturated fatty acids and *trans* fatty acids were all within their normal ranges, reducing the concern for dysinsulinemia and confirming LC's commitment to following dietary changes. He still required vitamins D and A. The dietary changes and supplement interventions reversed not only his presenting complaints, but radically improved the prognosis for his future health.

The RD/Nutritionist's Comments:

LC made remarkable changes, and he was very motivated to do so because he received the immediate feedback of improved health. Most notable, of course, was the resolution of the ADHD symptoms. LC's changes did not come overnight. Indeed, his was a "top-down" change, with his mother making the first moves toward wellness in her life, and experiencing the fruits of good health herself, and then bringing along her family. Wellness of this nature is an ecological shift, like a pebble tossed in a pond that ripples slowly to those around us.

I had been working with LC's mom for a long time before we saw LC. With his mom (as with most people), we started slowly. We did an initial clean-up of the worst (most problematic/toxic) foods in the house, and then removed one problem food per week from her diet. (Sometimes we would negotiate one food change a month. It's important to move at the patient's pace and ability to integrate change.)

Generally, when a child needs to make major dietary changes, it does require the family's buy-in. A significant move away from being unconscious about what we eat toward paying very close attention to where food comes from, what it's made of, the toxin and nutrient content, and the macronutrient composition requires a powerful and intentional return to our roots, how we evolved to eat. We must also pay attention to how we feel after we eat, and notice the impact of food on our health and well-being. We need to have everyone on board in the family, even if only a little, when thinking about food from this perspective. The home front is the nutritional frontier!

To succeed with such changes, the basics need to be addressed:

- ⊕ Where to shop/what to buy
- ⊕ How to avoid antigenic foods
- ⊕ How to replace the foods being eliminated from the diet with healthy alternatives
- ⊕ How to read and understand food labels
- ⊕ Identifying hidden food additives and antigens
- ⊕ “Natural” versus “organic”
- ⊕ Healthful, affordable foods
- ⊕ Easy, quick recipe ideas
- ⊕ Eating healthy on the go
- ⊕ Eating well at restaurants
- ⊕ Knowing the nutrient content of foods
- ⊕ Relying on foods, rather than supplements, for long-term nutrient needs
- ⊕ Understanding the appropriate balance and quantity of food
- ⊕ Stress-free eating: rest and digest
- ⊕ Resources for healthy eating: cookbooks, internet sites

The team approach to treatment in the case of LC was vital to his success. In addition to his medical doctor, he worked with me, a support RN, and of course his mother, father, and siblings. I am not sure we would have seen such a significant turnaround, as demonstrated by his writing specimens, without this approach to care.

Additional Forms

- ⊕ A completed Matrix form for LC is provided in Figure 3.
- ⊕ A convenient case-at-a-glance summary for LC is provided in Figure 4.

Figure 1:
LC's Pre-treatment Writing Sample

1. I wrote this sentence.
2. I have several radios.
3. Since when do you have an X box?
4. I am thinking of something.
5. I am better at math than my sister.
6. Though the cat was old, it was still very playful.
7. We're all in this together.
8. The water was calm until the alligator attacked.
9. Usually it is quiet in my room.
10. I am very happy most of the time.
11. While you were at school, I went skiing.
12. You ate the whole cake!!!
13. I went on a cruise on the English canal.
14. I am good at mathematics.
15. I listen to music a lot.
16. My Dad took a physical.
17. I have an education.
18. The old man was not very

Figure 3:
Completed Matrix Form for LC

Case at a Glance: ADHD

History of Present Illness

LC presented at age 12 with attention deficit hyperactivity disorder (ADHD), dysgraphia, environmental allergies, asthma, insomnia, eczema, canker sores, migraine headaches, muscle cramps, stomach pain, nausea, and diarrhea. LC was first diagnosed with ADHD at age 5. He repeated kindergarten because of attention and behavioral difficulties. He began methylphenidate (Ritalin®) in 1st grade and continued to take it through 4th grade, although his behavior did not change significantly. The drug was discontinued in 4th grade due to growth retardation. Off the medication, he gained weight and increased his intake of junk food and deli meats. He continued to have trouble focusing in school and was still disruptive. He had never received a positive teacher report. He had severe dysgraphia, but excelled in math. His medications included: cetirizine (Zyrtec®), albuterol, levalbuterol inhaler (Xopenex®), flunisolide (Nasarel or AeroBid®), cimetidine (Tagamet®), acetaminophen, and ibuprofen. He liked pasta, sweets, and ice cream despite the fact that he felt better avoiding dairy.

Abbreviated Assessments, Laboratory Findings and Treatments

Organized According to the Functional Medicine Matrix

(Refer to full case presentation for details, including treatment rationale.)

Clinical Assessment	Laboratory results	Recommended Treatment
LIFESTYLE FACTORS: NUTRIENT IMBALANCES		
Nutrient deficiencies Fatty acid imbalance Anxiety Muscle spasms Audio sensitivity Hyperkeratosis pilaris	Low essential minerals Low vitamins A, E, beta carotene Elevated AA:EPA ratio Low B6 (organic acid markers) Elevated saturated and trans fatty acids	Zinc citrate Magnesium glycinate Multivitamin/mineral EPA/DHA Pyridoxal 5' phosphate Dietary changes as noted below
IMMUNE SURVEILLANCE AND INFLAMMATORY PROCESS		
Hypovitaminosis D Food sensitivities Intestinal hyperpermeability ADHD Asthma, allergies, headache, hives, sinusitis Atopic dermatitis Aphthous stomatitis	Low serum vitamin D Multiple + IgG food sensitivities Elevated IgG antigliadin antibodies	Vitamin D3 Dietary changes: Modified elimination diet based on test results. No dairy, peanuts, gluten, sugar, or trans fatty acids. Reduce saturated fat intake. Whole foods, minimally processed, organic diet. (Nutritionist comments available in full case presentation.)
DIGESTION AND ABSORPTION		
Yeast overgrowth GERD, IBS, pruritus ani Nausea	Elevated lymphocyte:neutrophil ratio +IgG food sensitivities, IgG antigliadin antibodies	Fluconazole Broad spectrum probiotics
DETOXIFICATION AND BIOTRANSFORMATION		
Mild lead toxicity ADHD Food additives	Elevated 6-hour urine lead after 250 mg DMPS (2,3-dimercapto-1-propane-sulphonic acid) provocation	After 2 months on treatment protocol: Start DMSA (refer to full case presentation for details) Dietary changes as noted above
HORMONE AND NEUROTRANSMITTER REGULATION		
ADHD, dysgraphia Insomnia	Low-normal plasma tryptophan Low-normal urine HVA, 5HIAA	
6-Month Follow-up: LC's mother reported that he was free from his chronic symptoms for the first time in his life. His dysgraphia improved dramatically (compare Figures 1 and 2 in full case presentation). He no longer required his medications, including antihistamines (cetirizine and cimetidine), bronchodilators, steroid inhaler, acetaminophen, and ibuprofen. His mood and behavior stabilized, and his ability to focus improved greatly. His hyperactivity symptoms, including disruptiveness, irritability, and anxiety, were gone. His hives, asthma, runny nose and postnasal drip, anal itching, stomachaches, nausea, diarrhea, headaches, muscle cramps, and sensitivity to loud noises were all completely resolved. He slept soundly at night. He was doing well in school, academically and socially (see mother's comments in full case presentation). LC tolerated supplements and dietary changes well, because he felt so much better when he followed the plan.
